Experimental Section

Chemicals

Tin(IV) chloride(99.995%), iron(III) acetylacetone ($\geq 99.9\%$ trace metals basis), benzyl alcohol ($\geq 99\%$, reagentplus), graphite (powder, $<20\ \mu\text{m}$, synthetic), phosphorus pentoxide (99%, reagentplus) were purchased from Sigma-Aldrich. NaNO₃, H₂SO₄, KMnO₄, H₂O₂ and HCl were purchased from Samchun Chemical. All the chemicals were used as received.

Preparation of graphene oxide

Graphene oxide (GO) was produced from graphite powder following a modified Hummer's methods^{1 2}. Briefly, 1g of graphite powder was added to a mixture of 20mL of concentrated H₂SO₄, K₂S₂O₈ (2.5 g) and P₂O₅ (2.5 g). Then the solution was heated to 80 °C under stirring. After 5 hr, the mixture was filtered with DI water and dried at 70 °C leading to pre-oxidized graphite. Afterward, 1 g of the pre-oxidized graphite, 1 g of NaNO₃ and 46 mL of H₂SO₄ were stirred together in an ice bath for 2 hours. Then, 6 g of KMnO₄ were slowly added and reacted for 2 hours. After the mixture was stirred vigorously for 5 days at room temperature, 250 mL DI water was added. The solution was then slowly heated to 98 °C and maintained at this temperature for 1 hour. 6 mL of H₂O₂ (30 wt%) were slowly added and the solution was filtered and washed with 1:10 HCl aqueous solution (250 mL) to remove metal ions, followed by repeated washings with water. Finally the solid was separated by centrifugation and dried at 60 °C overnight.

Reduced graphene oxide or graphene nano-sheets (GNS) were either obtained by reduction of GO by a hydrothermal assisted treatment in presence of hydrazine (GNS1) or in benzyl alcohol under microwave irradiation at 185 °C for 10 min (GNS2).

Non-aqueous synthesis and graphene-composite synthesis

Under inert atmosphere, SnCl₄ or Fe(acac)₃ were added to 20mL of benzyl alcohol in a vial of total capacity of 35 mL, sealed with a Teflon cap and taken out of a glovebox. For the synthesis graphene/metal oxide composites, graphene oxide was also added to the

reaction mixtures. The solutions were homogenized by vigorous stirring for 30 seconds and sonication for 30 minutes. The solutions were then heated in a microwave (CEM Discovery SP). The experimental details of the different samples are summarized in Table 1. The resulting white (pure SnO₂) or black suspensions were centrifuged and the precipitate redispersed and washed with ethanol (once) and dichlromethane (twice). Subsequently, the powders were dried under vacuum for 1 hour.

Characterizations

Transmission electron microscopy (TEM) and high-resolution TEM (HRTEM) images were obtained on a JEOL EM-2010 and on a Tecnai F20 microscope at an accelerating voltage of 200 kV. Field Emission-Scanning Electron Microscopy (FE-SEM) investigations were carried out using a JEOL JSM-6701F. The powder X-ray diffraction (XRD) measurement was performed using a Rigaku D/Max-3C diffractometer (Cu K α radiation, $\lambda = 0.15418$ nm). The XPS experiments were performed in an UHV multipurpose surface analysis system (SIGMA PROBE, ThermoFisher Scientific, UK) operating at base pressures $<10^{-10}$ mbar. Fourier-transform IR (FT-IR) spectra were carried out through a Nicolet 6700 (Thermo Scientific, USA) in the infrared domain 400-4000 cm⁻¹ by a KBr matrix. For TGA measurements, a TA Instruments Simultaneous DTA/TGA analyser Q600 model was used with a heating rate 10 °C/min in air.

Electrochemical characterization

Working electrodes were prepared from all the samples (cf. Table 1), Super P (as a conducting agent) and polyvinylidene fluoride (PVDF, as a binder) (70:15:15 in weight ratio) in n-methyl-2-pyrrolidinone. The slurry was coated onto a copper foil current collector via doctor blade processing and then pressed for use as the working electrode. Electrochemical test cells were assembled in an argon-filled glove box using coin-type half-cells (2016 type) with lithium foil as a counter electrode. The organic electrolyte was composed of 1.0 M LiPF₆ in ethylene carbonate and diethyl carbonate (1:1 vol.%). The cells were galvanostatically charged and discharged in the voltage range from 2.0 to 0.01 V vs. Li⁺/Li in the SnO₂/grapheme case and from 3.0 to 0.01 V for the Fe₃O₄/graphene.

Electrochemical measurements were made with a WBCS3000 cycler (WonA Tech, Korea) at room temperature.
