Experimental methods

General

All reagents were used as received from Sigma-Aldrich. Oleylamine technical grade (70%, but 98% primary amines), *N,N*-Dimethylacetamide dimethyl acetal (90%), dimethylamine solution (2M in THF), gold chloride trace metal basis (99.9%). Solvents were used without further purification. Chloroform (99.5% with 0.5% ethanol as stabilizer) Multisolvent ® HPLC Grade ACS ISO UV-VIS and toluene (99.8%) HPLC Grade were purchased from Scharlau. Carbon dioxide (99.8%) was purchased from “Carburos Metálicos” (Air Products Group).

Characterization

¹H NMR and ¹³C NMR (CDCl₃ or D₂O) spectra were recorded on an AVANCE 400 MHz Bruker spectrometer. NMR data are reported in ppm, coupling constants in Hz and multiplicity as follows: singlet (s), doublet (d), triplet (t), quartet (q), or multiplet (m). UV-Vis spectra were recorded using a quartz cuvette (1x1x4 cm) in an Agilent-8543 spectrometer. Centrifugation was carried out in an Eppendorf Centrifuge 5804 R. Further sample characterization was performed by transmission electron microscopy (TEM) with a JEOL JEM-1010 instrument operated at 100 kV. To prepare TEM samples, a few drops of gold nanoparticles solution on carbon-coated copper grids (300 mesh), which was subsequently dried. Nanoparticle sizes were calculated by using ImageJ software.¹

Synthesis of gold nanoparticles. AuNPs were synthesized as previously described.² Briefly, AuCl (10 mg, 0.043 mmol) and oleylamine (395.9 μL, 0.860 mmol) were dissolved in CHCl₃ (2.15 mL) and heated at 67°C under reflux during 24 h. The resulting nanoparticles were precipitated with acetone (5 mL) and centrifuged at 8000 rpm for 5 min. The supernatant was removed, CHCl₃ (1 mL) and acetone (8 mL) were added again and the suspension was centrifuged under similar conditions. Once supernatant was removed, gold nanoparticles capped with oleylamine (Au@OA) were obtained and ready to be dissolved in the desired organic solvent.
