Section B. Determination of Binding Constant

Figure S8. Job plot for complexation between V-shaped compound **5** and the dumbbell 1-H·PF₆ (total conc = 20 mM) based on NMR spectroscopic data (\blacklozenge : observed; --: calcd).

2) Calculation of Binding Constant

With regard to the ¹H NMR spectroscopic method, the binding constant determination is classified into two categories—slow and fast exchanges, depending on the rate of equilibrium relative to NMR timescale. For slow-exchange equilibria, free and complexed hosts give separate signals. The stoichiometry, concentration of complex [C] and binding constant K can be calculated from peak integrations. For a rapidly exchanging system, free and complexed hosts appear as a weighted average. The stoichiometry can be determined from Job plot. A titration experiment and regression (Rose-Drago method) are required to evaluate [C]. Then, K can be calculated by curve-fitting.

For a host-guest complexation:

 $a \cdot H + b \cdot G \equiv C$ where H = Host, G = Guest, C = complex

$$K = \frac{[C]}{[H]^a \cdot [G]^b} \dots (1)$$

$$[H]_0 = [H] + a \cdot [C] \qquad \dots (2)$$

$$[G]_0 = [G] + b \cdot [C] \qquad ...(3)$$

K: Binding constant

a, *b*: Stoichiometry

- [H]₀: Initial (total) concentration of host molecule
- [G]₀: Initial (total) concentration of guest molecule

[H], [G], [C]: equilibrium concentrations of host, guest, and complex, respectively
