## Experimental

**Preparation of AuNPs:** In a 250mL round-bottom flask containing 50 mL water and put on magnetic heat stirrer (2 mot/min), 3.5mL of 1% trisodium citrate was added after the solution boiling. Then, a 500 $\mu$ L of 1% HAuCl<sub>4</sub> was added quickly and maintained the solution boiling. The color turned red within 5min and the final color change to brilliant red. Boiling continued for 10 min, the flask was removed from the heating source, and the colloid was not stirred until cold <sup>[1]</sup>. Last the solution of 57.3 $\mu$ g/mL Au was transferred to a 50 mL volumetric flask and diluted to 50 mL with water, and stored at 4°C. There is an absorption peak of 512 nm with an average size of 10 nm.

**Preparation of AgNPs:** A 5.0 g PEG10000 was added to an Erlenmeyer flask containing 70 mL water to make it dissolving. Then, a 7.0 mL 10 g/L trisodium citrate and 770  $\mu$ L 2.4 $\times$ 10<sup>-2</sup> mol/L AgNO<sub>3</sub> were added respectively. After that, 16.0 mL 0.25 mg/mL NaBH<sub>4</sub> was added slowly into the mixture under the vigorous stirring, during the time its color changed from pale yellow to deep yellow, which indicated that the nanosilver particles were formed <sup>[2]</sup>. 15 min later the mixture solution was diluted to 100 mL with water and stored in the refrigerator at 4°C, the concentration of silver particles was 19.9 mg/L with an average size of 10 nm and an absorption peak of 408 nm.

## Preparation of the oxidized Rh6G (ORh6G)

Into a 100mL round-bottom flask equipped with 2.5mL H<sub>2</sub>O, 25mL 0.01mol/L Rh6G solution, 10mL 0.5mol/L KBrO<sub>3</sub> solution, 10mL 1mol/L H<sub>3</sub>PO<sub>4</sub> solution, 2.5mL 1.45mmol/L NO<sub>2</sub><sup>-</sup> solution

and mixed well. The mixture heated at  $60^{\circ}\text{C}$  for 4h, after cooling in the tap water, the flask was removed to stand for 15min at room temperature. Taken the mixture solution into a 10.0mL centrifuge tube and centrifuged 30min ( $150\times 100\text{r/min}$ ), discarded the supernatant and taken the bottom sediment drying to obtain ORh6G power.

### Air sample preparation

**Fig.10S** was the sketch of air sampling device, collect time was 2.0 h and flow speed was 0.6L/min. The mainly components of nitrogen oxide (NOx) in the nature air were NO and  $\text{NO}_2$ , after oxidized by 10mL 0.16mol/L  $\text{KMnO}_4$  solution, the NOx almost complete to form  $\text{NO}_2$ , and the  $\text{NO}_2$  can be absorbed by 25mL 0.02mol/L NaOH solution to form  $\text{NO}_3^-$  and  $\text{NO}_2^-$  (Equation 2)<sup>[3]</sup>. After finish the air sample collection, neutralize the remained NaOH in the absorption solution until its pH in the range of 7.0-7.5 using 0.1mol/L HCl solution, and diluted to 50 mL and mixed well. Taken 200 $\mu\text{L}$  the sample solution to detect and added a known amount of  $\text{NO}_2^-$  solution into the water sample to obtain the recovery.

$$C_{\text{NO}_x} = n(\text{NO}_2) \times M(\text{NO}_2) / 2.0\text{h} \times 0.6\text{L} \cdot \text{min}^{-1} \quad (4)$$
