## Supplementary Information

$\mathrm{H}_{2} \mathrm{CO}_{3} \rightarrow \mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}$ Decomposition in Presence of $\mathrm{H}_{2} \mathrm{O}, \mathrm{HCOOH}$, $\mathbf{C H}_{3} \mathbf{C O O H}, \mathbf{H}_{2} \mathrm{SO}_{4}$ and $\mathrm{HO}_{2}$ Radical: Instability of the Gas-Phase $\mathbf{H}_{2} \mathrm{CO}_{3}$ Molecule in Troposphere and Lower Stratosphere

Sourav Ghoshal and Montu K. Hazra *
Chemical Sciences Division, Saha Institute of Nuclear Physics, 1/AF Bidhannagar, Kolkata-700 064, India

Table S1: Calculated total electronic energies ( $\mathrm{E}_{\text {totala }}$ ), zero point vibrational energy (ZPE) corrected total electronic energies [ $\mathrm{E}_{\text {total }}(\mathrm{ZPE})$ ] of the monomers, their complexes and transition states (TSs) at the MP2 level in conjunction with the aug-cc-pVDZ, aug-cc-pVTZ and 6-311++G(3df,3pd) basis sets as well as at the $\operatorname{CCSD}(\mathrm{T}) /$ aug-cc-pVTZ and M062X/aug-cc-pVTZ levels of theories. The values given in the first bracket correspond to the ZPE corrected total electronic energies. The ZPE correction in case of $\operatorname{CCSD}(\mathrm{T}) / \mathrm{aug}-\mathrm{cc}-\mathrm{pVTZ}$ level of calculations has been done from the MP2/aug-cc-pVTZ level predicted ZPE correction. Imaginary frequencies ( $v_{\mathrm{im}}$ ) of various transition states (TSs) are given in Table S2.

## Computational methodology, equations and atmospheric concentrations of the water monomer, dimer, $\mathrm{FA}, \mathrm{AA}, \mathrm{SA}$ and $\mathrm{HO}_{2}$ radical those have been used to estimate of the reaction rates of various pathways as have been discussed in the article:

For the $\mathrm{H}_{2} \mathrm{O},\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$, formic acid (FA), acetic acid (AA), sulphuric acid (SA) and hydroperoxide $\left(\mathrm{HO}_{2}\right)$ radical assisted decomposition pathways, as have been discussed in the text and where the isolated $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecule is directly involved in its decomposition, the decomposition reactions can be written in generalized form in terms of the bimolecular encounters between the $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecule and $\mathrm{X}\left(\mathrm{X} \equiv \mathrm{H}_{2} \mathrm{O},\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}, \mathrm{FA}, \mathrm{AA}, \mathrm{SA}\right.$, and $\left.\mathrm{HO}_{2}\right)$ as:

$$
\begin{equation*}
\mathrm{H}_{2} \mathrm{CO}_{3}+\mathrm{X} \underset{k_{-1}}{\stackrel{k_{1}}{\rightleftarrows}} \mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{X} \xrightarrow{k_{2}} \mathrm{CO}_{2} \cdots \mathrm{H}_{2} \mathrm{O} \cdots \mathrm{X} \rightleftarrows \mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}+\mathrm{X} \tag{1}
\end{equation*}
$$

The above reaction sequence is typically viewed as one involving the formation of the $\mathrm{H}_{2} \mathrm{CO}_{3}{ }^{\cdots} \mathrm{X}$ pre-reactive reactant complex ( $\mathbf{R C}$ ), which then undergoes unimolecular decomposition via the transition state (TS) to form the $\mathrm{CO}_{2} \cdots{ }^{\cdots} \mathrm{H}_{2} \mathrm{O}^{\cdots} \mathrm{X}$ product complex (PC) in the exit channel. Applying a steady state approximation to this pre-reactive reactant complex and assuming that it is in equilibrium with the reactants, the reaction rate (v) for the decomposition of $\mathrm{H}_{2} \mathrm{CO}_{3}$ in presence of a particular species ' X ' can explicitly be written including tunneling correction and reaction degeneracy as:

$$
\begin{gather*}
v=\sigma * \Gamma * \frac{k_{1}}{k_{-1}} * k_{2} *\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right] *[\mathrm{X}]=\sigma * \Gamma * K_{e q} * k_{2} *\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right] *[\mathrm{X}] \\
=K_{e q} * k_{2}^{\prime} *\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right] *[\mathrm{X}]=k *\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right] *[\mathrm{X}] \tag{2}
\end{gather*}
$$

$$
\begin{equation*}
\text { Where, } k_{2}^{\prime}=\sigma * \Gamma * k_{2} \quad \& \quad k=K_{e q} * k_{2}^{\prime} \tag{3}
\end{equation*}
$$

In the above equation, the $K_{\text {eq }}$ is the equilibrium constant of the pre-reactive complex, $k_{2}$ is the rate constant for the unimolecular reaction of the pre-reactive complex leading to the decomposition products, $\sigma$ is the reaction degeneracy and $\Gamma$ is the tunneling correction for the
reaction. Tunneling corrections are taken into account by assuming unsymmetrical Eckart barrier. ${ }^{1-4}$ The values of the equilibrium constant $\left(K_{e q}\right)$ for the pre-reactive complex can be calculated according to the equation 4 and the rate constant $\left(k_{2}\right)$ for the unimolecular reaction step involving the pre-reactive complex can be calculated by the conventional transition state theory (TST) according to the equation 5 , as given below: ${ }^{5-8}$

$$
\begin{align*}
& K_{e q}=\frac{Q_{R C}}{Q_{R_{t}} * Q_{R_{2}}} * e^{\frac{-\left(E_{R C}-E_{R}\right)}{R T}}  \tag{4}\\
& k_{2}=\frac{k_{b} T}{h} * \frac{Q_{T S}}{Q_{R C}} * e^{\frac{-\left(E_{T S}-E_{R C}\right)}{R T}} \tag{5}
\end{align*}
$$

In the above two equations, the various $Q$ denotes the product of electronic, translational, rotational and vibrational canonical partition functions referenced to the zero-point energy of the pre-reactive complex ( RC ), reactants $\left(\mathrm{R}_{1}\right.$ and $\left.\mathrm{R}_{2}\right)$ and transition state (TS). The $k_{b}$ and $h$ are respectively the Boltzmann and Planck constants, $T$ is the temperature in Kelvin, and $R$ is the ideal gas constant. Also, the $E_{R C}, E_{R}$ and $E_{T S}$ denote respectively the ZPE corrected energy of the prereactive complex, total energy of the isolated starting reactants $\left(R_{1}\right.$ and $\left.R_{2}\right)$ and energy of the transition state. Therefore, according to the above equations, the relative rate between the water monomer and FA assisted decompositions of the $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecule can be written as:

$$
\begin{equation*}
\frac{v_{\mathrm{H}_{2} \mathrm{O}}}{v_{\mathrm{FA}}}=\frac{\left(K_{e q}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}}}{\left(K_{e q}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{FA}}} * \frac{\left(k_{2}^{\prime}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}}}{\left(k_{2}^{\prime}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{FA}}} * \frac{\left[\mathrm{H}_{2} \mathrm{O}\right]}{[\mathrm{FA}]} \tag{6}
\end{equation*}
$$

Form the above equation, it is seen that the calculation is very much straightforward if the concentrations of the water and FA, which are basically the catalysts for the decomposition of $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecule, are known. Thus, one can easily evaluate the relative rates for the decompositions of the $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecule in presence of the $\mathrm{H}_{2} \mathrm{O},\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}, \mathrm{FA}$, AA, SA and $\mathrm{HO}_{2}$ radical; as the concentration of these species in the Earth's atmosphere are known. However, we note that this equation does not work in similar way for other bimolecular reactions those have been considered
for the decomposition of the $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecule in presence of the two and/or three water molecules, in particular, in the pathways where the decompositions of the $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecules starts from the $\mathrm{H}_{2} \mathrm{CO}_{3}{ }^{\cdots} \mathrm{H}_{2} \mathrm{O}$ or $\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O} \cdots \mathrm{H}_{2} \mathrm{O}$ complexes. This follows as the concentrations of the $\mathrm{H}_{2} \mathrm{CO}_{3}{ }^{\cdots} \mathrm{H}_{2} \mathrm{O}$ or $\mathrm{H}_{2} \mathrm{CO}_{3}{ }^{\cdots} \mathrm{H}_{2} \mathrm{O} \cdots \mathrm{H}_{2} \mathrm{O}$ complexes are also not known. However, these unknown concentrations of the complexes can be expressed by their equilibrium constants and the concentrations of the reactants those form these complexes in terms of bimolecular encounters. For an example, in the case of $\mathrm{H}_{2} \mathrm{CO}_{3}$ decomposition in presence of the two water molecules with the pathways where second water molecule function either actively or passively to stabilize the prereactive $\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}$ complex obtained in the water monomer assisted $\mathrm{H}_{2} \mathrm{CO}_{3}$ decomposition, the decomposition reaction in terms of bimolecular encounters can explicitly be written as:

$$
\begin{equation*}
\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}+\mathrm{H}_{2} \mathrm{O} \rightleftarrows \mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O} \cdots \mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{CO}_{2} \cdots\left(\mathrm{H}_{2} \mathrm{O}\right)_{3} \rightleftarrows \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O} \tag{7}
\end{equation*}
$$

In the above reaction, the reaction rate for the decomposition of $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecule via $\mathrm{H}_{2} \mathrm{CO}_{3}{ }^{\cdots} \mathrm{H}_{2} \mathrm{O}$ complex or the atmospheric loss of the $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecule depends upon the unknown concentration of the $\mathrm{H}_{2} \mathrm{CO}_{3}{ }^{\cdots} \mathrm{H}_{2} \mathrm{O}$ complex. However, as mentioned above that the unknown concentration of the $\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}$ complex can be expressed by the equilibrium constant for the formation of the $\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}$ complex, the relative rate between the single water molecule assisted $\mathrm{H}_{2} \mathrm{CO}_{3}$ decomposition and the two water molecules assisted $\mathrm{H}_{2} \mathrm{CO}_{3}$ decomposition according to the pathways of the Reaction-7, as described above, can be written in terms of the equilibrium constant for the formation of the $\mathrm{H}_{2} \mathrm{CO}_{3}{ }^{\cdots} \mathrm{H}_{2} \mathrm{O}$ complex and the concentrations of the $\mathrm{H}_{2} \mathrm{CO}_{3}$ and $\mathrm{H}_{2} \mathrm{O}$ reactants as:

$$
\frac{v_{\left(\mathrm{H}_{2} \mathrm{O}\right)}}{V_{\left(2 \mathrm{H}_{2} \mathrm{O}\right)}}=\frac{\left(K_{e q}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}}}{\left(K_{e q}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O} \cdots \mathrm{H}_{2} \mathrm{O}}} * \frac{\left(k_{2}^{\prime}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}}}{\left(k_{2}^{\prime}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \cdots \mathrm{H}_{2} \mathrm{O}}} * \frac{\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right] *\left[\mathrm{H}_{2} \mathrm{O}\right]}{\left[\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}\right] *\left[\mathrm{H}_{2} \mathrm{O}\right]}
$$

$$
\begin{gather*}
=\frac{\left(K_{e q}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}}}{\left(K_{e q}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \cdots \mathrm{H}_{2} \mathrm{O}}} * \frac{\left(k_{2}^{\prime}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}}}{\left(k_{2}^{\prime}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \cdots \mathrm{H}_{2} \mathrm{O}}} * \frac{1}{\left(K_{e q}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}}} * \frac{1}{\left[\mathrm{H}_{2} \mathrm{O}\right]} \\
=\frac{1}{\left(K_{e q}\right)_{\mathrm{H}_{2} \mathrm{CO} 3} \cdots \mathrm{H}_{2} \mathrm{O} \cdots \mathrm{H}_{2} \mathrm{O}} * \frac{\left(k_{2}^{\prime}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \mathrm{O}}}{\left(k_{2}^{\prime}\right)_{\mathrm{H}_{2} \mathrm{CO}_{3} \cdots \mathrm{H}_{2} \cdots \mathrm{H}_{2} \mathrm{O}}} * \frac{1}{\left[\mathrm{H}_{2} \mathrm{O}\right]} \tag{8}
\end{gather*}
$$

Therefore, we find from the above equation that the calculation of the relative rate between the water monomer assisted $\mathrm{H}_{2} \mathrm{CO}_{3}$ decomposition and the two water molecules assisted $\mathrm{H}_{2} \mathrm{CO}_{3}$ decompositions according to the Reaction 7 is also straightforward if the concentration of the water molecule is known. It is worthwhile to note that the equilibrium constant for the formation of the $\mathrm{H}_{2} \mathrm{CO}_{3}{ }^{\cdots} \mathrm{H}_{2} \mathrm{O} \cdots \mathrm{H}_{2} \mathrm{O}$ complex can easily be evaluated by equation 4, as given above. We follow the same approach in case of other various pathways associated with the $\mathrm{H}_{2} \mathrm{CO}_{3}$ decompositions in presence of the three water molecules. In essence, we note that the relative rates of all the pathways discussed in the article can easily be evaluated if one takes the water monomer and/or water dimer assisted $\mathrm{H}_{2} \mathrm{CO}_{3}$ decomposition reactions as the references. In Table S 3 to S 8 , we present the overall rate constants $\left(k=k_{2}{ }^{\prime} * K_{\text {eq }}\right)$ including the reaction degeneracy and tunneling corrections for all the pathways associated with decompositions of the $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecule. Note that no tunneling correction has been done for the AA assisted $\mathrm{H}_{2} \mathrm{CO}_{3}$ decomposition reaction at MP2/aug-cc-pVTZ level of theory, as effective barrier is negative (see text). It is also to be noted here that in our calculations, we have not used any reaction degeneracy ( $\sigma$ ) in predicting the equilibrium constants for the formation of $\mathrm{H}_{2} \mathrm{O} \cdots \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{H}_{2} \mathrm{CO}_{3}{ }^{\cdots} \mathrm{H}_{2} \mathrm{O}$ complexes. However, when we have considered single water molecule as a reactant in the decomposition reactions in terms of bimolecular encounters, the value of $\sigma=2$ has been used in predicting the overall rate constants. ${ }^{9}$

It has been mentioned in the text that in order to assess the impacts of various decomposition pathways, it is necessary to compare the reaction rates rather than the reaction rate constants. Therefore, given that the rates for all the pathways, discussed above, can be expressed easily with respect to the rate of the water monomer or dimer assisted $\mathrm{H}_{2} \mathrm{CO}_{3}$ decomposition reaction, we next
estimate the concentrations of the water monomer and dimers in the Earth's atmosphere up to 15 km altitude from the Earth's surface ( 0 km altitude). It is worthwhile to note here that the focus of our work is only to the decompositions of $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecule in the Earth's troposphere and lower stratosphere. In Table S9, we provide the estimated concentrations of the water monomers and dimers in the $0-15 \mathrm{~km}$ altitude range. The concentrations of water dimers have been estimated by following equation 4, as given above. It is seen from the Table $S 9$ that our calculated values for both the water monomers and dimers at different altitudes match well with the values reported in the literature. ${ }^{10-12}$ In Table S9, we also provide the concentrations of the $\mathrm{FA}, \mathrm{AA}, \mathrm{SA}$ and $\mathrm{HO}_{2}$ radical those have been reported in the literature or from the graphical estimates, where the measured values of the concentrations or the mixing ratios are not available directly. ${ }^{13-31}$ In case of the FA, we note that two atmospheric profiles are available in terms of the two different ranges of FA concentrations and these two profiles have been reported separately by Razavi ${ }^{13}$ and Shephard et al. ${ }^{14}$ Importantly, while the atmospheric profile reported by Razavi et al. ${ }^{13}$ shows that the mixing ratios of the FA in the altitude range 0 to 15 km are always below 1 ppbv , the mixing ratios of the FA in the same altitude range according to the profile reported by Shephard et al. ${ }^{14}$ are always above 1 ppbv . Therefore, in our relative rate calculations, we take the average values of the FA concentrations according to these two profiles. On the other hand, in case of AA, we don't find atmospheric profiles like those have been reported for the FA. However, we note that the most of the measurements of AA mixing ratios have been reported for the Earth's surface and for lower altitudes of the Earth's atmosphere. ${ }^{16,19-26}$ In most of the cases, we find that the mixing ratios of the FA and AA are similar and in other some cases, the mixing ratios of the AA are little bit higher than the mixing ratios of the FA. ${ }^{19-26}$ Therefore, to compare the FA and AA assisted $\mathrm{H}_{2} \mathrm{CO}_{3}$ decompositions on equal footing; the concentrations for both the FA and AA have been taken same in the $0-15 \mathrm{~km}$ altitude range. Indeed, and in particular, we note that the reported value for the average AA mixing ratio ${ }^{15}$ at 0 km altitude is $\sim 3.8 \mathrm{ppbv}$ and this value matches with the average value ( $\sim 3.56 \mathrm{ppbv}$ ) that we have obtained from the two atmospheric profiles, as mentioned above. It is also worthwhile to note here that this average concentration of the FA or AA at 0 km altitude, which we have taken into account in our rate
calculations, is approximately and at least 4 to 5 times higher than the measured concentrations of the FA or AA present in the clean environment of the Earth's atmosphere (see text).

Table S3: Equilibrium constants ( $K_{\text {eq }}$ ) for the formation of pre-reactive complexes, rate constants $\left(k_{2}\right)$ of the unimolecular reactions, tunnelling corrections $(\Gamma$ ) and overall rate constants $(k)$ at the MP2/aug-cc-pVTZ level of calculations for the decompositions of $\mathrm{H}_{2} \mathrm{CO}_{3}$ in presence of the water monomer and dimer. The units of $K_{\text {eq }}, k_{2}$ and $k$ are respectively $\mathrm{cm}^{3} /$ molecule, $\mathrm{sec}^{-1}$ and $\left(\mathrm{cm}^{3} /\right.$ molecule) $\mathrm{sec}^{-1}$. The decompositions of $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecule in presence of the water monomer and dimer have been labelled as R-I and R-II, as mentioned in the text. The values given in the parenthesis correspond to the results predicted at the $\operatorname{CCSD}(\mathrm{T}) /$ aug-cc-pVTZ level of calculations.

Table S4: Equilibrium constants ( $K_{\text {eq }}$ ) for the formation of pre-reactive complexes, rate constants $\left(k_{2}\right)$ of the unimolecular reactions, tunnelling corrections $(\Gamma)$ and overall rate constants $(k)$ at the MP2/aug-cc-pVTZ level of calculations for the decompositions of $\mathrm{H}_{2} \mathrm{CO}_{3}$ in presence of the two water molecules those are associated with the RC-II, RC-III and RC-IV and reaction pathways respectively R-IIa, R-III and R-IV. The reaction path: R-IIa is corresponding to the path where the two water molecules actively assist the $\mathrm{H}_{2} \mathrm{CO}_{3}$ decomposition by a common pre-reactive complex (RC-II). The units of $K_{e q}, k_{2}$ and $k$ are respectively $\mathrm{cm}^{3} /$ molecule, $\mathrm{sec}^{-1}$ and ( $\left.\mathrm{cm}^{3} / \mathrm{molecule}\right) \mathrm{sec}^{-1}$.

Table S9: Concentrations (molecules/ $\mathrm{cm}^{3}$ ) of the water monomer $\left(\mathrm{H}_{2} \mathrm{O}\right)$, dimer $\left[\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$, formic acid (FA), acetic acid (AA), sulfuric acid (SA) and hydroperoxide $\left(\mathrm{HO}_{2}\right)$ radical at different altitude of the Earth's atmosphere. For the calculations of water monomer concentrations in the 0 to 15 km altitude of the Earth's atmosphere, the temperatures ( $T$ ), pressures ( P ), air density and mixing ratios (M.R) of water monomers have been taken from ref. 12. The concentrations of water dimers at different altitudes have been estimated by the use of equation 4 , as given above, based on the MP2/aug-cc-pVTZ level predicted energies and anharmonic frequencies. In the calculation of the relative reaction rates, the average values of FA and AA concentrations have taken into account and same concentrations have been used, as has been mentioned above.

Table S12: The M06-2X/aug-cc-pVTZ level predicted and ZPE corrected electronic energies ( $\Delta \mathrm{E}_{\text {corr }}$ ) and free energies ( $\Delta \mathrm{G}$ at 298.15 K ) of the pre-reactive complexes ( RC ) and transition states (TS) involved in the water monomer, formic acid and acetic acid assisted $\mathrm{H}_{2} \mathrm{CO}_{3}$ decomposition reactions. The energies ( $\mathrm{kcal} / \mathrm{mol}$ ) of pre-reactive complexes and transition states (TS) have been determined with respect to the total energies of the isolated starting reactant monomers $\left(\mathrm{H}_{2} \mathrm{CO}_{3}+\mathrm{X}\right)$ involved in bimolecular encounters. The values marked with blue colour are taken from the works of Kumar et al. (Ref-32-33) for a comparison at the same level of theory. The free energy barriers $\left(\Delta \mathrm{G}^{\#}\right)$ for the unimolecular decomposition steps have been shown separately to avoid the confusion from the effective free energy barriers (free energy of TS with respect to total free energies of starting isolated bimolecular reactants) of the $\mathrm{H}_{2} \mathrm{CO}_{3}$ decomposition reactions.

Table S13: M06-2X/aug-cc-pVTZ level calculated reaction rates (v) for both the $\mathrm{H}_{2} \mathrm{O}$ and formic $\operatorname{acid}(\mathrm{HCOOH})$ assisted $\mathrm{H}_{2} \mathrm{CO}_{3}$ decomposition reactions at 298.15 K in the unit of $\sec ^{-1}$. The values of the equilibrium constants ( $K_{\text {eq }}$ ) for the formation of pre-reactive complexes and rate constants ( $k_{2}$ ) of the unimolecular decomposition steps have been given respectively in the unit $\mathrm{om}^{3} /$ molecule and $\sec ^{-1}$. In table, the $\Gamma$ represent the tunnelling corrections for the respective reactions and the predicted relative rate is based upon the concentrations (molecule $/ \mathrm{cm}^{3}$ ) of water and FA those have been reported by Kumar et al. (Ref-32). The values in parenthesis indicated by blue colour have also been shown as reported by Kumar et al. in their correction paper (Ref-33).

| $\begin{gathered} 2.7 \\ (10.0) \\ \hline \end{gathered}$ |  |  |  |  |

As mentioned above, we have calculated the values of $K_{e q}$ and $k_{2}$ according to the equation 4 and 5 (see above). It is to be noted here that the resultant value of the ( $K_{e q} \times k_{2}$ ) can also be calculated directly if we multiply the equation 4 and 5 and use resultant equation ${ }^{32}$ that does not involve the energy and partition function of the pre-reactive complex. In addition, for further verification of our data, one can use following three equations ${ }^{8}$ as given below to calculate the values equilibrium constants ( $K_{e q} \equiv K_{c}$ ) and unimolecular decomposition rate constants ( $k_{2}$ ) according the free energy values of the pre-reactive complexes and transition states, as given in the Table S12.

$$
\begin{align*}
& K_{p}=\exp \left(\frac{-\Delta \mathrm{G}_{\mathrm{f}}}{\mathrm{RT}}\right)  \tag{9}\\
& K_{e q}=K_{c}=K_{p} *(\mathrm{RT})^{-\Delta \mathrm{n}}  \tag{10}\\
& k_{2}=\left(\frac{k_{b} \mathrm{~T}}{\mathrm{~h}}\right) * \exp \left(\frac{-\Delta \mathrm{G}^{\#}}{\mathrm{RT}}\right) \tag{11}
\end{align*}
$$

In the above equations, $\Delta \mathrm{G}_{\mathrm{f}}$ and $\Delta \mathrm{G}^{\#}$ are respectively the free energy change of the pre-reactive complex when it is formed from the isolated starting bimolecular reactants and free energy barrier for the unimolecular decomposition step in the unit of $\mathrm{kcal} / \mathrm{mol}$. Like before, the $\mathrm{k}_{\mathrm{b}}, \mathrm{h}$ and R are respectively the Boltzmann constant, Planck's constant and universal gas constant. The unit of $K_{p}$
and $K_{c}$ are respectively $(\mathrm{atm})^{-1}$ and $\left(\mathrm{cm}^{3} /\right.$ molecule), and $\Delta \mathrm{n}$ is the change in number of moles when a pre-reactive complex is formed from the bimolecular isolated starting reactants.
