#### *Table of contents*

1. Analysis of water content by Karl Fischer coulometry.
2. GC-MSD analysis results
3. Analysis of CH<sub>4</sub>/H<sub>2</sub> according to reaction time
4. Methanol production according to reaction time

1. Water content analysis by Karl Fischer coulometry

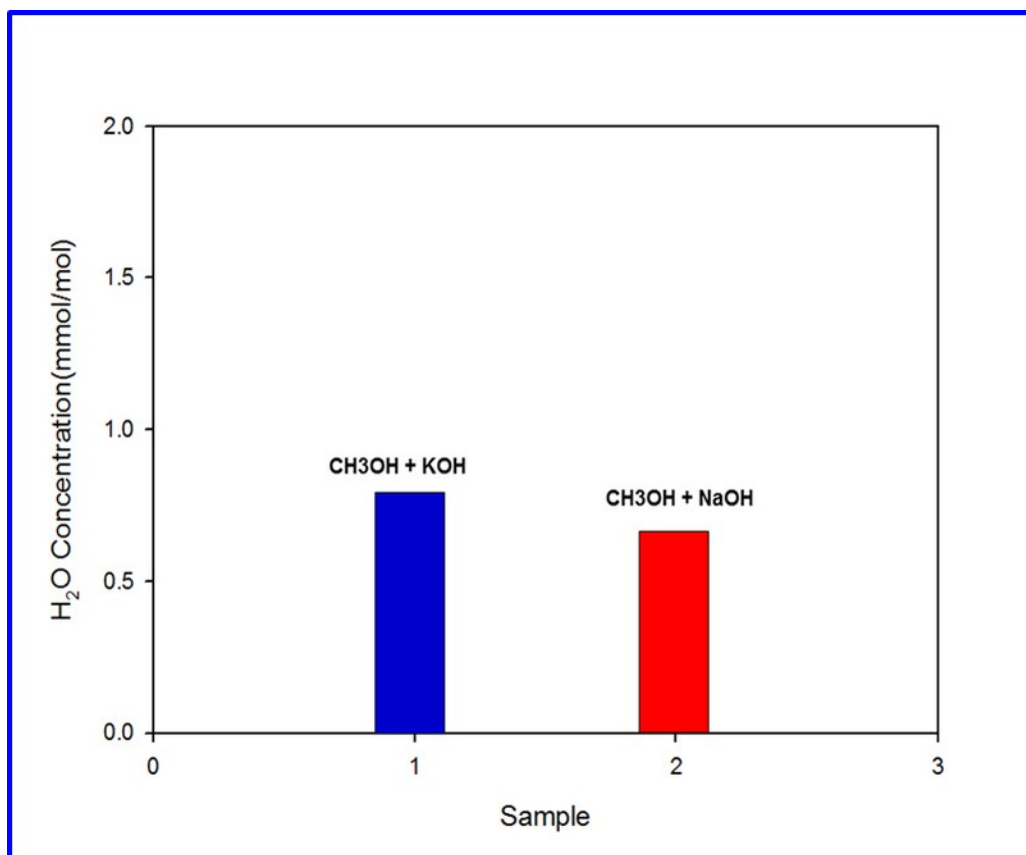

Figure S1. Concentrations of water generated from the dissolved 0.2 M KOH or 0.2 M NaOH with methanol (115 mL) at 25°C.

Figure S1 is the result of the analysis of water concentrations after the dissolution reaction of 0.2 M KOH or 0.2 M NaOH with methanol using a Karl Fischer Coulometer. Dissolution of KOH with CH<sub>3</sub>OH produced a higher water concentration in comparison to that of CH<sub>3</sub>OH and with CH<sub>3</sub>OH.

## 2. GC-MSD analysis results

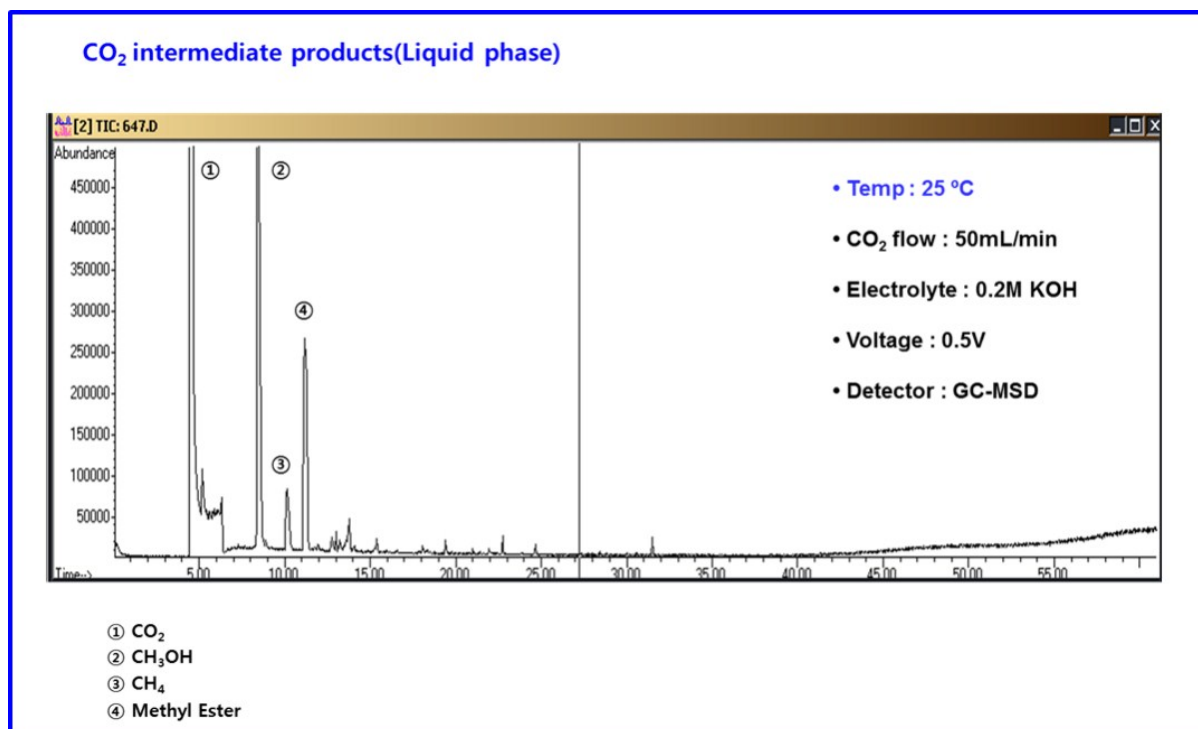

Figure S2. GC-MSD chromatogram for reduction in 0.2 M KOH at a CO<sub>2</sub> flow rate of 50 mL·min<sup>-1</sup> and applied voltage of 0.5 V at 25°C.

Figure S2 is presents a product analysis using GC-MSD. Other than the final product, CH<sub>4</sub>, only methyl ester was determined. The non-diaphragm electrochemical system produces only H<sub>2</sub> and CH<sub>4</sub>. The same products were determined for reaction times of 1 to 5 h.

### 3. Analysis of CH<sub>4</sub>/H<sub>2</sub> according to reaction time

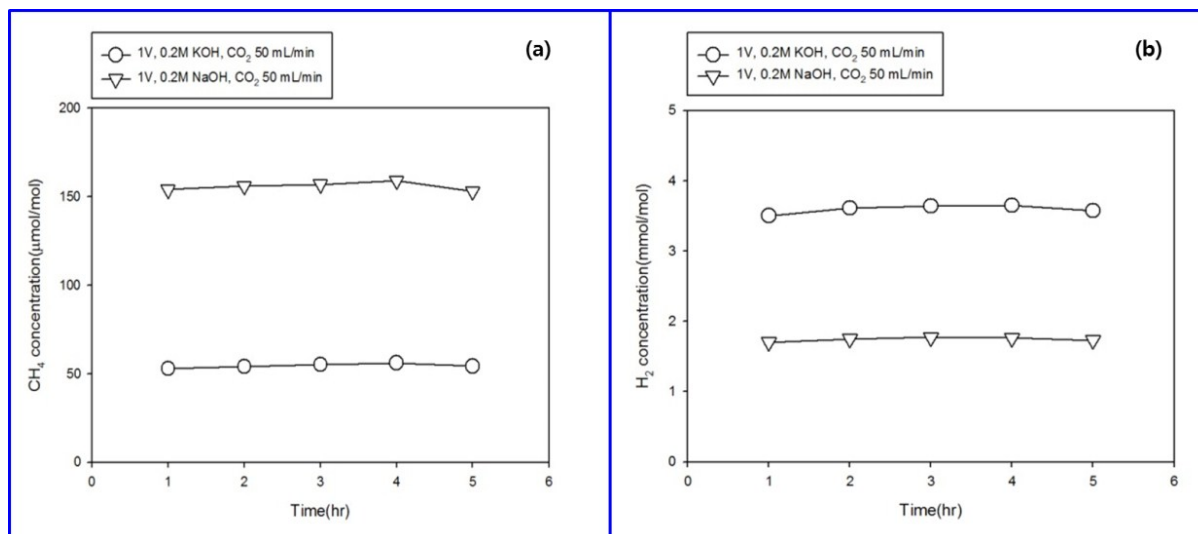

Figure S3. Comparison of CH<sub>4</sub>/H<sub>2</sub> production over time in a non-diaphragm-based electrochemical system at a CO<sub>2</sub> flow rate of 50 mL·min<sup>-1</sup> and applied voltage of 0.5 V at 25°C with different electrolytes. (a), CH<sub>4</sub> concentration (GC-FID); and (b), H<sub>2</sub> concentration (GC-TCD).

Figure S3 presents the analysis of concentrations of CH<sub>4</sub>/H<sub>2</sub> according to the reaction time. The pattern is nearly as constant as a steady state, and the products differ according to additional electrolytes (NaOH and KOH). As shown in Figure S3, CH<sub>4</sub> is the main product when NaOH is used as an electrolyte, while H<sub>2</sub> is the main product when KOH is used as an electrolyte. The results indicate that using NaOH and KOH may select the type of product. Only CH<sub>4</sub> and H<sub>2</sub> are the products throughout the CO<sub>2</sub> reduction reaction, as shown in Fig S2, and we thus confirm the advantage of a non-diaphragm-based electrochemical system.

4. Methanol production according to reaction time

Figure S4. Comparison of methanol concentration produced in non-diaphragm-based electrochemical system at a CO<sub>2</sub> flow of 50 mL·min<sup>-1</sup> and applied voltage of 0.5 V at 25°C with different electrolytes: 0.2 M KOH (inverted triangles) and 0.2 M NaOH (closed circles).

Figure S4 documents the CH<sub>3</sub>OH concentrations over time after the application of voltage. At 1 h, the CH<sub>3</sub>OH concentration decreases due to dissolution reaction with NaOH and KOH. However, CH<sub>3</sub>OH is not degraded electrochemically because the concentration is constant with the extended reaction time.
