Experimental Details

Unless otherwise stated, all manipulations were performed under an inert dinitrogen or helium atmosphere. 1,3,5-Tris(2*H*-tetrazol-5-yl)benzene hydrochloride (H₃BTT·2HCl) was prepared according to the literature procedure.¹ All other reagents were obtained from commercial vendors and used without further purification. *Caution*. Tetrazolate compounds are potentially explosive, and should be handled with care. While we did not encounter any difficulties in handling the free ligand H₃BTT·2HCl or the frameworks derived therein, care should be taken to avoid generating sparks or creating friction on the material. In particular, a teflon-lined spatula should be used when handling the desolvated form of Fe-BTT.

Fe₃[(Fe₄Cl)₃(btt)₈]₂·22DMF·32DMSO·11H₂O (solvated FeBTT). Anhydrous ferrous chloride (76 mg, 0.59 mmol), H₃BTT·2HCl (58 mg, 0.20 mmol), DMF (5 mL), and DMSO (5 mL) were added to a 20 mL scintillation vial, and the vial was tightly sealed with a teflon-lined cap. The reaction mixture was heated on a hotplate at 110 °C for 24 h, after which time small, pale yellow crystals were formed on the vial walls. The solid was filtered and washed with DMF, and isolated as a pale vellow-green solid (42 mg, 32%). IR (neat): 3391 (m br), 3002 (w), 2920 (w), 1654 (s), 1498 (w), 1435 (m), 1412 (s), 1389 (m), 1314 (w), 1253 (w), 1227 (w), 1194 (w), 1102 (w), 1014 (s), 951 (s), 904 (m), 788 (s), 749 (m), 661 (w). Anal. Calcd for C₂₇₄H₄₁₆Cl₆Fe₂₇N₂₁₄O₆₅S₃₂: C, 31.36; H, 4.00; N, 28.56. Found: C, 31.19; H, 4.05; N, 28.32. The solvent composition was deduced using a combination of elemental analysis data and thermogravimetric analysis. The DMF-solvated framework was generated by suspending 1 within DMF at 80 °C for 24 h, with exchanging of the solvent for fresh DMF each 8 h. IR (neat): 3178 (br s), 2927 (m), 2857 (m), 1656 (s) 1498 (m), 1437 (m), 1408 (s), 1385 (s), 1254 (m), 1090 (s), 1062 (m), 951 (w), 907 (w), 865 (w), 788 (m), 749 (w), 696 (w), 678 (w), 658 (s). The methanol-solvated framework was generated by suspending the DMF-solvated material in MeOH at 100 °C for 48 h, exchanging the solvent for fresh MeOH each 8 h. IR (neat): 3178 (br s), 2943 (m), 2831 (m), 1416 (s), 1231 (w), 1194 (w), 1133 (w), 1069 (w), 1012 (s), 902 (w), 789 (s), 750 (m), 688 (w), 645 (w). The sample is air- and moisture-sensitive, and was stored in a solvent-free glove box under dinitrogen.

High-Throughput Experiments. High-throughput experiments were performed using a robotic Symyx Core Module System equipped with powder- and liquid-dispensing functionality. The main features of the robot deck are shown in Figure S1. The recipes for the screening reactions were programmed from a client computer terminal using Symyx Library Studio version 7.1.7.14, and the automated dispensing protocols were executed through Symyx Automation Studio version 1.1.1.8. These client-side software applications communicate to the Core Module through a central server, which maintains a database containing all experimental parameters. The Core Module is loaded within a Braun glovebox under a dinitrogen atmosphere, and the pneumatic valves were operated using a dinitrogen supply with a pressure maintained at 80 psi.

Powder dispensing was performed by loading finely-ground metal salts and ligands into plastic powder-dispensing hoppers. The solid was dispensed by automatic transfer of the individual vials onto a Sartorius LP 1200.S balance on the Core Module deck with a measurement error of less than 0.1 mg. Stability of the balance was achieved through sealing of the balance headspace using a polymer membrane with a circular opening that allows for lowering of the powder hopper to a position just above the aperture of the vial. Following taring of the weight of the empty vial, the appropriate quantity of solid was dispensed by the robot arm. The discrepancy between the mass dispensed and the programmed mass was typically within 2%.

Liquid dispensing was achieved by firstly placing vials filled with neat solvents on the robot deck in positions as input in the Automation Studio protocol. The vials were sealed with scepta to avoid cross-contamination or evaporation of the solvents. The liquids were aspirated through a needle that is located on the right arm, and is connected to a series of three syringe pumps with volumes of 0.5 mL, 3 mL, and 5 mL, respectively. The syringe used depended upon the quantity of the liquid to be dispensed. Once the liquid is aspirated, the needle is moved to the appropriate vials through movements of the right arm. The protocol was such that the needle was thoroughly washed with methylene chloride following each solvent, to avoid cross-contamination.

Automated dispensing of the products onto glass plates for powder X-ray analysis was achieved by a protocol that firstly aspirates the mother liquid from the reaction product, and replenishes it the vial with fresh DMF. This procedure was repeated three times, followed by a similar washing procedure using methylene chloride. The crystals were then pulverized using the automated shaker system on the robot deck with small ball bearings, and the resulting slurry was dispensed into individual wells of a crystallizer block attached to a glass plate. The methylene chloride was then allowed to evaporate, and the crystallizer block was removed from the glass plate. The plate was then mounted onto a metal frame, and subsequently transferred to the high-throughput powder diffractometer.

X-ray Structure Determination. A block-shaped single-crystal of solvated Fe-BTT (0.1 mm \times 0.1 mm) was coated in Paratone-N oil, attached to a Kapton loop, and mounted on a Bruker X8 APEX diffractometer equipped with a Bruker MICROSTAR Cu rotating anode X-ray source. The sample was cooled to 100 K under a stream of nitrogen, and preliminary cell data were obtained to yield a cubic Laue group. A full hemisphere of data was collected over a period of 24 h, after which time the crystal showed no significant decomposition or structural distortion. Data were integrated and corrected for Lorentz, polarization, and absorption effects within the APEX 2 software package. Crystal and refinement parameters are listed in Table S1. Space group determinations were made based on systematic absences, *E* statistics, and successful refinement of the structure. The structure solution was obtained using direct methods and the SHELXS-97 software, and expanded through successive difference Fourier maps. Thermal parameters for all non-hydrogen atoms were refined anisotropically, and hydrogen atoms were assigned to ideal positions using the appropriate AFIX commands. Complete modeling of the solvent within the pores was not possible due to disorder, hence the electron density within the cavities was masked using the SQUEEZE routine within the PLATON software package.²

Accessible Surface Area Calculation. The source code for the accessible surface area calculation program was obtained free of charge from the Internet.³ The crystallographic information file (CIF) obtained from the single crystal X-ray structure was converted to the XYZ file format using Mercury CSD 2.0. The XYZ file and UFF force field atomic parameters⁴ were used as input for the simulation (atomic diameters (Å): H 2.571, C 3.431, N 3.260, O 3.118, Fe 2.594, Cl 3.516), and the accessible surface area was evaluated using a dinitrogen-sized probe molecule (diameter = 3.681 Å) inserted at randomized points in the unit cell, and averaging the resultant individual accessible surface area values after 5000 trials.

Mössbauer Spectroscopy. The Mössbauer spectrum of Fe-BTT was measured at various temperatures between 10 and 295 K in a Janis Supervaritemp cryostat with a constant-acceleration spectrometer which utilized a rhodium matrix cobalt-57 source, and was calibrated at 295 K with α -iron powder. The absorber contained 32 mg/cm² of powder mixed with boron

nitride. The absorber was prepared and inserted into the cryostat under dry dinitrogen. The relative statistical errors associated with the isomer shifts, quadrupole splittings, line widths, percent areas, and absolute areas measured between 10 to 225 K was ± 0.005 , ± 0.01 , ± 0.01 mm/s, 0.2 %, and 0.3 (% ϵ)(mm/s), respectively; these statistical errors are approximately twice as large between 260 and 295 K. The absolute errors of these parameters were approximately twice the statistical errors.

Powder Neutron Diffraction Experiments. Neutron powder diffraction data were collected on the High Resolution Neutron Powder Diffractometer BT-1 at the NIST Center for Neutron Research (NCNR) with a Ge-(311) monochromator and using in-pile collimation of 15 min of arc, corresponding to a wavelength of 2.0787 Å. Measurements were taken as a function of deuterium loading at a temperature of 4 K with measurement times of ca. 9 h for the bare framework and D₂ loadings of 4.1, 8.0 D₂ molecules per formula unit, and ca. 5 h for all higher D₂ loadings.

All sample transfers were performed in a helium-filled glovebox equipped with water and oxygen monitors. Initial sample activation was performed in a glass tube with a packless bellows valve attached. The sample was evacuated using a turbomolecular pump (10^{-5} Torr) and heated to 135 °C with a ramp speed of ca. 0.5 °C per minute. After degassing at 135 °C for 16 h, the sample was cooled and transferred to a cylindrical vanadium can (i.d. 0.95 cm) equipped with a capillary gas line and a packless valve, and sealed with a lead O-ring. The sample was mounted onto a sample stick equipped with a stainless-steel gas line with an additional valve for a top-loading closed-cycle helium refrigerator. The sample was further degassed in situ for ca. 20 min under high vacuum. During the experiments, a known amount of hydrogen (deuterium) gas was loaded into the sample (813 mg), which was maintained at a temperature of 60 K until no pressure drop was observed for at least 1 min. The sample was then cooled down to the base temperature of 3.5 K over a period of 1 h in order to perform measurements. In all cases, the outgas pressure reading was zero well before reaching 25 K.

A diffraction pattern was collected for Fe-BTT prior to dosing with D_2 . Subsequent Rietveld analysis indicated the existence of extra neutron density close to the Fe²⁺ ions in the framework skeleton, as expected due to the presence of residual methanol molecules. Accordingly, the extra neutron density was modeled using a partial occupancy of methanol O and C atoms, and this corrected "bare" model was used as a baseline for all subsequent measurements involving D_2 . A significant quantity of nuclear density was observed in a position approximately 4.23 Å above the chloride ion, which could be modeled as extraframework Fe atoms with the correct occupancy to fulfill charge balance of the anionic framework.

Neutron scattering diffraction patterns were analyzed using the Rietveld refinement method. The program EXPGUI incorporating the Rietveld program GSAS⁵ was used to perform all refinements. The model of the bare material was refined first, and it was used as the starting point for subsequent refinements of the D₂-loaded samples. Deuterium molecules are treated as point scatters with double occupancy since they are expected to be quantum mechanically averaged in the ground state. As mentioned, during the refinement of the model for the bare material, extra C and O atoms were introduced to account for the scattering intensities from the residual methanol molecules bound to the intraframework Fe²⁺ ions. The information on the extra atoms was obtained from the diffraction pattern of the bare material and was fixed at these values when analyzing the cases with deuterium molecules loaded. The coordinates of all other atoms and the Debye-Waller factors were allowed to vary during the refinement of each deuterium loading case. Based on the structure obtained from the diffraction pattern of the bare material, the diffraction patterns of the first D₂-loaded case (4 D₂ molecules/formula unit) was analyzed by firstly neglecting the D₂ molecules. The Fourier difference maps were calculated, clearly indicating the positions of D₂ adsorption sites. Accurate values for the D₂ locations and occupancy numbers were then obtained by Rietveld refinement. For each successive D₂ loading, the Fourier difference map was calculated on the basis of the results of the previous D₂ loading and used to identify new D₂ adsorption sites.

Inelastic Neutron Scattering Experiments. Inelastic neutron scattering data were collected on the Filter Analyzer Neutron Spectrometer (FANS) BT-4 at the NCNR. The same sample can from the diffraction experiment was used and was cooled in the same manner as the neutron diffraction experiments.

Low-Pressure Gas Sorption Measurements. Glass sample tubes of a known weight were loaded with approximately 200 mg of sample, and sealed using a TranSeal. Samples were degassed at 135 °C for 24 h on a Micromeritics ASAP 2020 analyzer until the outgas rate was no more than 1 mTorr/min. The degassed sample and sample tube were weighed precisely and then transferred back to the analyzer (with the TranSeal preventing exposure of the sample to the air after degassing). The outgas rate was again confirmed to be less than 1 mTorr/min. Adsorption

isotherms were measured at 77 K in a liquid nitrogen bath for H_2 and N_2 , and at 87 K in a liquid argon bath for H_2 .

High-Pressure Gas Sorption Measurements. In a typical measurement, at least 200 mg of sample was loaded in a sample holder in a glove box under an argon atmosphere. The sample was evacuated at 130 °C for 10 h under a pressure of less than 10⁻⁵ torr. Hydrogen excess adsorption measurements were performed on an automated Sieverts' apparatus (PCTPro-2000 from Hy-Energy Scientific Instruments LLC) over a pressure range of 0-100 bar. UHP-grade hydrogen and helium (99.999% purity) were used for all measurements. Volumetric measurements at 77 K were carried out by submerging the sample holder in a liquid nitrogen bath, for which the fill-level was maintained constant throughout the experiment.

The total adsorption, C_{tot} was calculated using the following relationship;

$$C_{tot} = C_{exc} + \frac{100 \times d_g V_{pore}}{1 + d_g V_{pore}}$$

where C_{exc} is the excess uptake, d_g represents the density of pure H₂ gas calculated from an isothermal equation of state,⁶ V_{pore} is the pore volume of the sample. V_{pore} is readily calculated from the experimental skeletal density of the sample, d_{sk} , and the crystallographically determined bulk density of the sample, d_{bulk} , using the expression below;

$$V_{pore} = \frac{d_{sk} - d_{bulk}}{d_{sk} d_{bulk}}$$

The total volumetric uptake, C_{vol} , was calculated by;

$$C_{\rm vol} = Q_{ads} d_{bulk}$$

where Q_{ads} represents the total H₂ adsorbed (in mmol/g). Alternatively, the excess volumetric uptake can be calculated if the excess quantity of H₂ is used in place of Q_{ads} .

Other Physical Measurements. Powder X-ray diffraction patterns were obtained on a Bruker D8 Advance diffractometer with a Cu anode ($\lambda = 1.5406$ Å), or in the case of the high-throughput experiments a Bruker D8 Discover with GADDS. Infrared spectra were obtained on a Perkin-Elmer Spectrum 100 Optica FTIR spectrometer furnished with an attenuated total reflectance accessory (ATR). Carbon, hydrogen, and nitrogen analyses were obtained from the Microanalytical Laboratory at the University of California, Berkeley. Thermogravimeteric analyses (TGA) were performed on a TA Instruments TGA 5000 instrument at a ramp rate of 2 °C/min under a flow of nitrogen.

Table S14. Higher-pressure H₂ adsorption data in an activated sample of Fe-BTT at 298 K.

Figure S1. A view of the Symyx Core Module robot deck. The left arm consists of a gripper for holding the powder dispensing heads (circular containers in the center), and the right arm is equipped with a gripper for transferring the vials from one of the six plate positions on the right of the deck, to the balance (circular opening at the left). Liquid dispensing occurs through movements of the right arm, and the aspiration of solvents occurs through the three syringe pumps at the back of the deck.

Figure S2. A view of the custom-designed 96-vial plate loaded with 1 mL vials. The plates are placed in one of the six plate positions on the robot deck shown in Figure S1, and can be heated, cooled, or stirred according to the parameters within the experiment protocol.

Figure S3. The location of the extraframework ions within Fe-BTT as determined by neutron diffraction. Orange, green, blue, and gray spheres represent Fe, Cl, N, and C atoms, respectively. Hydrogen atoms have been omitted for clarity. The occupancy of the extraframework ions is approximately 1/8.

Figure S4. Adsorption isotherm for N_2 in an activated sample of Fe-BTT recorded at 77 K.

Figure S5. A BET plot of the adsorption isotherm for N_2 in Fe-BTT at 77 K, where *x* represents the quantity (P/P₀) and *V* is the volume of N_2 adsorbed. The blue line represents a linear best fit of the data points. Inset: parameters for the linear best fit and resulting constants for calculation of the BET surface area.

Figure S6. Powder X-ray diffraction patterns of Fe-BTT: simulated from the single crystal X-ray structure (black), of the as-synthesized solvated material (red), and the methanol-exchanged material (blue).

Figure S7. Rietveld refinement of neutron powder diffraction data for an evacuated sample of Fe-BTT. Green lines, crosses, and red lines represent the background, experimental, and calculated diffraction patterns, respectively. The blue line represents the difference between experimental and calculated patterns. The final Rietveld fit parameter was $\chi^2 = 1.271$.

Figure S8. Rietveld refinement of neutron powder diffraction data for loading of 4 D₂ molecules per formula unit of Fe-BTT. Green lines, crosses, and red lines represent the background, experimental, and calculated diffraction patterns, respectively. The blue line represents the difference between experimental and calculated patterns. The final Rietveld fit parameter was $\chi^2 = 1.154$.

Figure S9. Rietveld refinement of neutron powder diffraction data for loading of 20 D₂ molecules per formula unit of Fe-BTT. Green lines, crosses, and red lines represent the background, experimental, and calculated diffraction patterns, respectively. The blue line represents the difference between experimental and calculated patterns. The final Rietveld fit parameter was $\chi^2 = 1.177$.

Figure S10. Rietveld refinement of neutron powder diffraction data for loading of 33 D₂ molecules per formula unit of Fe-BTT. Green lines, crosses, and red lines represent the background, experimental, and calculated diffraction patterns, respectively. The blue line represents the difference between experimental and calculated patterns. The final Rietveld fit parameter was $\chi^2 = 0.9606$.

Figure S11. Rietveld refinement of neutron powder diffraction data for loading of 65 D₂ molecules per formula unit of Fe-BTT. Green lines, crosses, and red lines represent the background, experimental, and calculated diffraction patterns, respectively. The blue line represents the difference between experimental and calculated patterns. The final Rietveld fit parameter was $\chi^2 = 1.140$.

Figure S12. Rietveld refinement of neutron powder diffraction data for loading of 98 D₂ molecules per formula unit of Fe-BTT. Green lines, crosses, and red lines represent the background, experimental, and calculated diffraction patterns, respectively. The blue line represents the difference between experimental and calculated patterns. The final Rietveld fit parameter was $\chi^2 = 0.9473$.

Figure S13. Thermogravimetric analysis of as-synthesized Fe-BTT up to a temperature of 500 °C, as measured using a ramping rate of 2 °C/min.

Figure S14. Thermogravimetric analysis of methanol-exchanged Fe-BTT up to a temperature of 550 °C, as measured using a ramping rate of 2 °C/min.

Figure S15. Fitting of the hydrogen adsorption data recorded at 77 K (blue) and 87 K (red) using a virial type function. Inset: virial parameters used for the fitting to the data.
