## 1 Computational methodology

The structural model was cut out of the crystal structure of the [FeFe] hydrogenase from *Clostridium pasteurianum* (pdb code: 3C8Y).<sup>1</sup> The oxygen atom of the bridging dithiolate ligand in the [2Fe]<sub>H</sub> subcluster was replaced by NH.<sup>2–4</sup> The extraction of the QM region leads to dangling bonds where the connection to the protein was cut. Hydrogen atoms were added at a distance of 1.096 Å to saturate the generated dangling bonds in a way that the bond direction of the original bond was retained. The added hydrogen atoms and the first carbon atoms of the QM model were kept fixed during structure optimization. This procedure maintains the directional constraints imposed by the protein matrix. In addition, the backbone atoms (C<sub>α</sub>, C, O and N) of residues 232, 324 and 325, which are contained in the model, were kept fixed during structure optimization. The capping hydrogen atoms of the backbone parts were allowed to relax during structure optimization.

The structures haven been optimized in vacuo and the gradient convergence criterion was set to 10<sup>−4</sup> hartree/bohr for the length of the geometry gradient. Single-point calculations were performed with the COSMO electrostatic continuum model<sup>5</sup> and  $\epsilon = 4$ , as is often done to model the screening effect of a protein (see, e.g., Ref. 6). For iron a modified (COSMO) radius of 1.391 Å was chosen, as suggested in Ref. 7. The SCF convergence criterion was tightened (10<sup>−7</sup> hartree) compared to the default value (10<sup>−6</sup> hartree).

Frequencies were calculated from the analytic Hessian of the electronic energy with the aforce program of the TURBOMOLE program package. However,

---

aoforce does not allow for a special treatment of frozen atoms. Thus, some normal modes always feature imaginary frequencies originating from these structural constraints. Because of the frozen atoms in our structural models, some normal modes always feature imaginary frequencies. These imaginary frequencies are generally low and well separable from modes corresponding to transition states. As a consequence, only differences in energy and not differences in free energy are obtained, since the imaginary frequencies would introduce significant errors in free energy calculations (apart from the fact that the standard quantum-mechanical rigid-rotor, harmonic-oscillator, particle-in-a-box model is rather poor for enzymatic reactions). The modulation of reaction energies and barrier heights calculated from electronic energies is usually small and can even be on the order that the standard approximation introduces (the rigid-rotator, harmonic-oscillator, particle-in-a-box approximation) applied in quantum chemical calculations may become inappropriate for the condensed phase and thus at the reaction center of an enzyme under physiological conditions. To calculate the energetics of enzymatic reactions from electronic energies has thus become the standard approach (quantum mechanical cluster approach<sup>8</sup>).

The antiferromagnetic coupling pattern was enforced by exchange of iron atoms after the first converged SCF procedure (see e.g. Ref. 9). The two iron atoms of the cubane proximal to the [2Fe]<sub>H</sub> subcluster were coupled antiferromagnetically to the two iron atoms of the cubane distal to the [2Fe]<sub>H</sub> subcluster. If there was spin density on the [2Fe]<sub>H</sub> subcluster, it was coupled antiferromagnetically to the two proximal iron atoms of the cubane. This coupling pattern was investigated in detail by Fiedler and Brunold.<sup>10</sup>

The calculated frequencies were not scaled, as the scaling factors for the BP86 functional in combination with a proper triple-zeta basis with polarization functions would be close to one.<sup>11–13</sup> Reduction energies are calculated as difference in electronic energy of the optimized structures with the charge of the product increased by –1.

## 2 Effect of the H cluster surrounding amino acids on intermediate 3

The effect of the amino-acid residues surrounding the H cluster, especially the effect of the salt bridge from Lys358 to CN<sup>–</sup> at Fe<sub>d</sub>, can be illustrated at the example of intermediate **3**. The structure of intermediate **3** is shown in Figure 1 (top structure). The CN<sup>–</sup> forms a salt bridge to Lys358 (as discussed for intermediates **0'** and **0''** in the main article). This salt bridge leads to a high stability of the conformation shown in Figure 1. Optimization of a model of intermediate **3** consisting of the H cluster only leads to the structure denoted **3**<sub>small</sub> in Figure 1. In contrast to the large model, the cyanide ligand is in the apical position and forms a salt bridge to the bridgehead's ammonium group. For the small model a conformation of intermediate **3** which resembles the conformation of intermediate **3** of the large model (**3'**<sub>small</sub>) is obtained by swapping the two

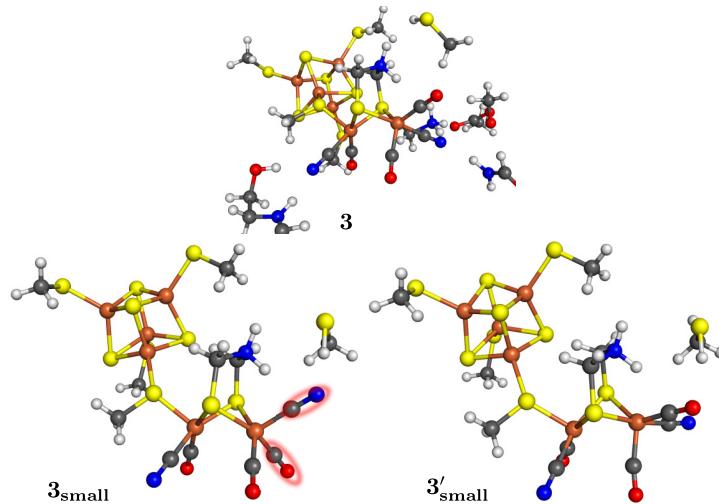

Figure 1: Top structure: Most stable structure of intermediate **3** obtained with the large model. Bottom left structure: Most stable conformation of intermediate **3** with a model only consisting of the H cluster (**3<sub>small</sub>**). Bottom right structure: Conformation of intermediate **3** which is obtained when exchanging the two ligands marked in red of **3<sub>small</sub>** (dubbed **3'<sub>small</sub>**). **3<sub>small</sub>** is  $-4.0\text{ kcal/mol}$  more stable than **3'<sub>small</sub>**. All structures were optimized with the BP86-D3/def2-TZVP. Electronic energies were obtained in BP86-D3/def2-TZVP/COSMO( $\epsilon = 4$ ) single-point calculations on optimized structures.

ligands marked in red in Figure 1. However, this conformation is  $4.0\text{ kcal/mol}$  less stable than **3<sub>small</sub>**. Hence, the salt bridge from Lys358 to CN<sup>-</sup> at Fe<sub>d</sub> is crucial for interlocking the conformation of the H cluster in the enzyme.

### 3 Additional reactions of the terminal-H species

Two pathways for  $\mu$ -H formation are investigated in detail in the main article which we consider most likely from a chemical point of view. In order to investigate whether other reaction pathways are also possible for  $\mu$ -hydride formation we explored additional reactions. Due to a lack of other proton donors in the vicinity of  $\mu$ -bridging position than Lys358, direct protonation via another pathway than protonation by Lys358 can be excluded. Thus, only reactions of the terminal-H species (intermediate **4**) remain to be investigated. A possible reaction would be the shift of the hydride (as proton) to one of sulfur atoms of the dithiolate ligand accompanied by the reduction of Fe<sub>p</sub> and Fe<sub>d</sub>. This reaction is endothermic by  $+17.5\text{ kcal/mol}$  for the sulfur atom distal to Lys358 and endothermic by  $+14.3\text{ kcal/mol}$  for the sulfur atom proximal to Lys358. We estimated the barrier with a reaction coordinate scan to be about  $28.3\text{ kcal/mol}$  for the latter reaction. The barrier is approximately as high as for the iso-

merization of terminal-H to  $\mu$ -H but the reaction is endothermic. Hence, this pathway is unlikely. Insertion of the hydride between  $\text{Fe}_d$  and the  $\text{CN}^-$  ligand to form HCN might be possible as well. However, all structure optimization of the HCN product converged to a terminal-H structure which shows that this reaction is not possible. Finally, we scanned the position of the hydride on a grid around its equilibrium position with single-point calculations to identify possible other low-energy routes. Figure 2 shows plots of the electronic energy surface for the nucleus position of the hydrogen atom shifted away from  $\text{Fe}_d$ . Displacements of the hydride lead to a steep increase of the energy. Hence, hydride abstraction reactions seem unlikely. Reactions involving cleavage of the hydride were also excluded by other authors, see e.g. Ref. 14. By contrast, in the rearrangement reaction from terminal-H to  $\mu$ -H — as described in the main article — the hydride is always bound to  $\text{Fe}_d$ . Thus, it can safely be assumed that this rearrangement process is favored compared to reactions which involve hydride abstraction.

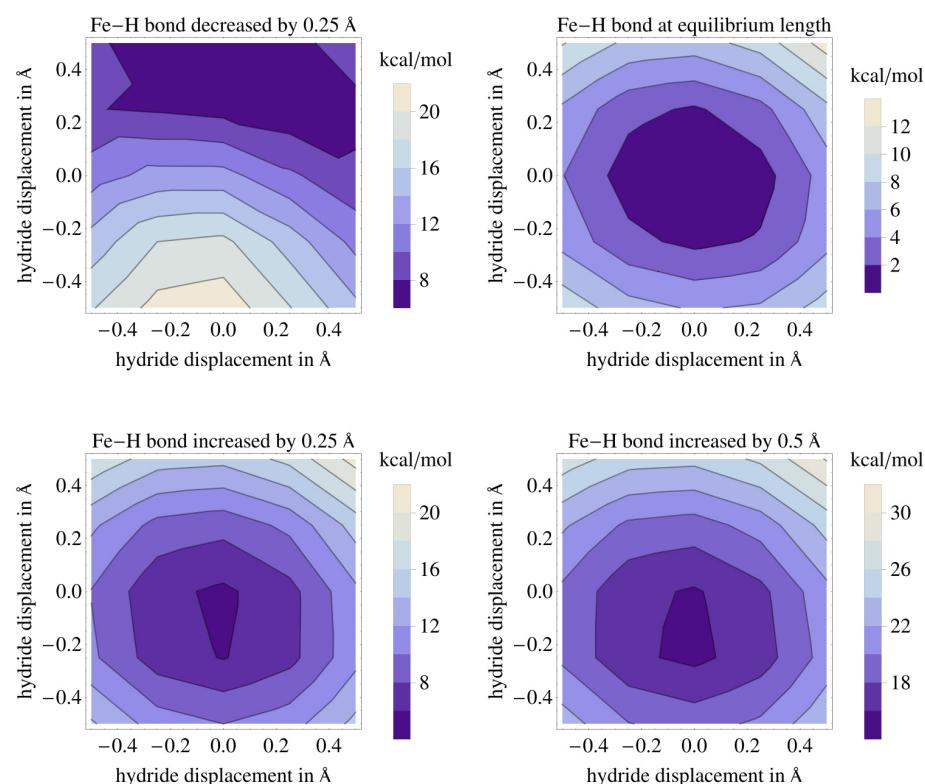

Figure 2: The hydride position at intermediate **4** was changed in the plane defined by the two sulfur atoms and the CO's carbon atom in the square plane around  $\text{Fe}_\text{d}$ . The position of the hydride was changed with a  $0.25\text{\AA}$  step size. The scan was performed for the equilibrium bond length decreased by  $0.25\text{\AA}$  (top left panel), for the equilibrium bond length (top right panel), for the equilibrium bond length increased by  $0.25\text{\AA}$  (bottom left panel), and for the equilibrium bond length increased by  $0.5\text{\AA}$  (bottom right panel). The energies are given relative to the energy of the equilibrium structure. The single point calculations were conducted without COSMO.
