## Synthesis and Characterization of New Selenourea Compounds

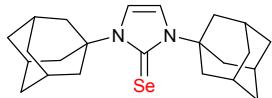

**General.** The selenoureas of IPr, SIPr, IMes, SIMes,  $\text{IPr}^{\text{OMe}}$ ,  $\text{SIPr}^{\text{OMe}}$ ,  $\text{IPr}^*$ ,  $\text{IPr}^{*\text{OMe}}$ ,  $\text{IPr}^{\text{Cl}}$  and  $\text{I}^{\text{i}}\text{Pr}^{\text{Me}}$  have been reported previously.<sup>1-3</sup> Imidazolium salts and free NHCs were prepared in-house using literature procedures.<sup>4-7</sup> KO'Bu, K<sub>2</sub>CO<sub>3</sub> and Se were used as received. THF was dried and degassed using an in-house solvent purification system. Chloroform-*d* and acetone-*d*<sub>6</sub> were used as received. Reactions were set up under an argon atmosphere in septum-fitted screw-cap vials, and worked up in the fume hood with bench-grade solvents (DCM, pentane). Bench grade solvents were also used to crystallize samples for X-ray analysis. NMR analyses were carried out using 11.7 T NMR spectrometers equipped with a BBFO-*z*-ATMA probe (<sup>1</sup>H observe at 500 MHz; <sup>19</sup>F observe at 470 MHz; <sup>13</sup>C observe at 126 MHz; <sup>77</sup>Se observe at 95 MHz) or a QNP-*z* probe (<sup>1</sup>H observe at 500 MHz; <sup>13</sup>C observe at 126 MHz). <sup>1</sup>H NMR spectra were referenced to the residual solvent signals and <sup>13</sup>C{<sup>1</sup>H} NMR spectra were referenced to the resonances corresponding to the deuterated solvent,<sup>8</sup> while <sup>77</sup>Se{<sup>1</sup>H} spectra were referenced externally to (PhSe)<sub>2</sub> and <sup>19</sup>F{<sup>1</sup>H} NMR spectra were referenced externally to CFCl<sub>3</sub>. *Safety note: selenium is highly toxic, and should be handled with care. In these experiments, solvents were removed carefully on the Schlenk line in a fume hood, and all contaminated materials were cleaned carefully or disposed of via a separate waste stream.*

**Method A (from the imidazolium salt).** The NHC salt (*ca.* 50 mg, weighed accurately) and KO'Bu (*ca.* 1.2 – 1.8 equiv.) were weighed into a vial. Excess Se (*ca.* 30 mg) was added, followed by a stirrer bar, and the vial was purged with Ar. Dry, degassed THF (1 mL) was added *via* the septum and the resulting suspension was stirred at room temperature overnight.

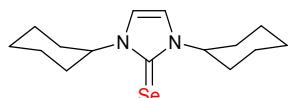

**Method B (from the triazolium salt).** The NHC salt (*ca.* 50 mg, weighed accurately) and *ca.* 5 equiv. K<sub>2</sub>CO<sub>3</sub> were weighed into a septum-fitted vial, followed by excess Se (*ca.* 30 mg) and a stirrer bar. The vial was purged with Ar, dry and degassed THF (1 mL) was added *via* the septum and the resulting suspension was stirred at room temperature overnight.

**Method C (from the free NHC).** In an argon-filled glovebox, the free NHC was weighed into a screw-cap vial and dissolved in dry, degassed THF. On the Schlenk line, this solution was transferred *via* cannula to an oven-dried and Ar-purged vial containing excess Se and a stirrer bar. The resulting suspension was stirred at room temperature overnight.

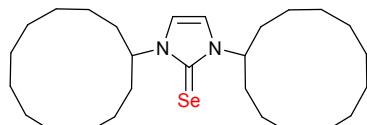

**Work-up.** The solvent was evaporated and the resulting residue was suspended in DCM (*ca.* 2 mL) and filtered through a pad of celite. The pad was washed with further DCM (*ca.* 2 mL). The DCM was evaporated and the residue was washed with pentane (3 x *ca.* 1 mL). The IHept and INon derivatives are pentane-soluble so were not washed in this way. The resulting solids were dried under high vacuum to yield material that was pure by elemental analysis (C, H, N within 0.4% of the calculated values).

## X-ray Crystal Structure Data for Selenourea Compounds

### [Se(IAd)]

#### *Experimental*

##### Data Collection

A colorless prism crystal of  $C_{23}H_{32}N_2Se$  having approximate dimensions of  $0.120 \times 0.050 \times 0.050$  mm was mounted in a loop. All measurements were made on a Rigaku XtaLAB P200 diffractometer using multi-layer mirror monochromated Mo-K $\alpha$  radiation.

Cell constants and an orientation matrix for data collection corresponded to a primitive orthorhombic cell with dimensions:

$$a = 23.300(2) \text{ \AA}$$

$$b = 7.0807(7) \text{ \AA}$$

$$c = 11.6415(13) \text{ \AA}$$

$$V = 1920.6(3) \text{ \AA}^3$$

For  $Z = 4$  and F.W. = 415.48, the calculated density is  $1.437 \text{ g/cm}^3$ . Based on the reflection conditions of:

$$0kl: k+l = 2n$$

$$h0l: h = 2n$$

packing considerations, a statistical analysis of intensity distribution, and the successful solution and refinement of the structure, the space group was determined to be:

$$Pna2_1 (\#33)$$

The data were collected at a temperature of  $-100 \pm 1^\circ\text{C}$  to a maximum  $2\theta$  value of  $50.8^\circ$ . Readout was performed in the 0.172 mm pixel mode.

##### Data Reduction

Of the 22163 reflections were collected, where 3522 were unique ( $R_{\text{int}} = 0.0402$ ); equivalent reflections were merged. Data were collected and processed using CrystalClear (Rigaku).<sup>1</sup>

The linear absorption coefficient,  $\mu$ , for Mo-K $\alpha$  radiation is  $19.651 \text{ cm}^{-1}$ . An empirical absorption correction was applied which resulted in transmission factors ranging from 0.746 to 0.906. The data were corrected for Lorentz and polarization effects.

### Structure Solution and Refinement

The structure was solved by heavy-atom Patterson methods<sup>2</sup> and expanded using Fourier techniques. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using the riding model. The final cycle of full-matrix least-squares refinement<sup>3</sup> on  $F^2$  was based on 3522 observed reflections and 235 variable parameters and converged (largest parameter shift was 0.00 times its esd) with unweighted and weighted agreement factors of:

$$R1 = \sum |||F_O| - |F_C||| / \sum |F_O| = 0.0238$$

$$wR2 = [\sum (w(F_O^2 - F_C^2)^2) / \sum w(F_O^2)^2]^{1/2} = 0.0568$$

The goodness of fit<sup>4</sup> was 1.01. Unit weights were used. Plots of  $\sum w(|F_O| - |F_C|)^2$  versus  $|F_O|$ , reflection order in data collection,  $\sin \theta/\lambda$  and various classes of indices showed no unusual trends. The maximum and minimum peaks on the final difference Fourier map corresponded to 1.05 and -0.15 e<sup>-</sup>/Å<sup>3</sup>, respectively. The final Flack parameter<sup>5</sup> was 0.007(4), indicating that the present absolute structure is correct.<sup>6</sup>

Neutral atom scattering factors were taken from International Tables for Crystallography (IT), Vol. C, Table 6.1.1.4<sup>7</sup>. Anomalous dispersion effects were included in  $F_{\text{calc}}$ <sup>8</sup>; the values for  $\Delta f'$  and  $\Delta f''$  were those of Creagh and McAuley<sup>9</sup>. The values for the mass attenuation coefficients are those of Creagh and Hubbell<sup>10</sup>. All calculations were performed using the CrystalStructure<sup>11</sup> crystallographic software package except for refinement, which was performed using SHELXL2013<sup>12</sup>.

#### Data Collection

A colorless prism crystal of C<sub>15</sub>H<sub>24</sub>N<sub>2</sub>Se having approximate dimensions of 0.150 x 0.120 x 0.040 mm was mounted in a loop. All measurements were made on a Rigaku XtaLAB P200 diffractometer using multi-layer mirror monochromated Mo-Kα radiation.

Cell constants and an orientation matrix for data collection corresponded to a primitive monoclinic cell with dimensions:

$$a = 11.8147(15) \text{ \AA}$$

$$b = 11.1443(13) \text{ \AA} \quad \beta = 108.210(3)^\circ$$

$$c = 12.2088(14) \text{ \AA}$$

$$V = 1527.0(3) \text{ \AA}^3$$

For Z = 4 and F.W. = 311.33, the calculated density is 1.354 g/cm<sup>3</sup>. The reflection conditions of:

$$h0l: l = 2n$$

$$0k0: k = 2n$$

uniquely determine the space group to be:

$$P2_1/c (\#14)$$

The data were collected at a temperature of -100  $\pm$  1°C to a maximum 2θ value of 50.8°. Readout was performed in the 0.172 mm pixel mode.

### Data Reduction

Of the 18233 reflections were collected, where 2808 were unique ( $R_{\text{int}} = 0.0483$ ); equivalent reflections were merged. Data were collected and processed using CrystalClear (Rigaku).<sup>1</sup>

The linear absorption coefficient,  $\mu$ , for Mo-Kα radiation is 24.463 cm<sup>-1</sup>. An empirical absorption correction was applied which resulted in transmission factors ranging from 0.766 to 0.907. The data were corrected for Lorentz and polarization effects.

### Structure Solution and Refinement

The structure was solved by heavy-atom Patterson methods<sup>2</sup> and expanded using Fourier techniques. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using the riding model. The final cycle of full-matrix least-squares refinement<sup>3</sup> on  $F^2$  was based on 2808 observed reflections and 163 variable parameters and converged (largest parameter shift was 0.00 times its esd) with unweighted and weighted agreement factors of:

$$wR2 = [\sum (w(F_O^2 - F_C^2)^2) / \sum w(F_O^2)^2]^{1/2} = 0.0998$$

The goodness of fit<sup>4</sup> was 1.05. Unit weights were used. Plots of  $\sum w(|F_O| - |F_C|)^2$  versus  $|F_O|$ , reflection order in data collection,  $\sin \theta/\lambda$  and various classes of indices showed no unusual trends. The maximum and minimum peaks on the final difference Fourier map corresponded to 0.89 and -0.42 e<sup>-</sup>/Å<sup>3</sup>, respectively.

Neutral atom scattering factors were taken from International Tables for Crystallography (IT), Vol. C, Table 6.1.1.4<sup>5</sup>. Anomalous dispersion effects were included in  $F_{\text{calc}}$ <sup>6</sup>; the values for  $\Delta f'$  and  $\Delta f''$  were those of Creagh and McAuley<sup>7</sup>. #### Data Collection

A colorless prism crystal of C<sub>27</sub>H<sub>48</sub>N<sub>2</sub>Se having approximate dimensions of 0.210 x 0.060 x 0.030 mm was mounted in a loop. All measurements were made on a Rigaku XtaLAB P200 diffractometer using multi-layer mirror monochromated Mo-K $\alpha$  radiation.

Cell constants and an orientation matrix for data collection corresponded to a primitive monoclinic cell with dimensions:

$$a = 14.4058(13) \text{ \AA}$$

$$b = 7.4133(7) \text{ \AA} \quad \beta = 97.856(3)^{\circ}$$

$$c = 25.023(3) \text{ \AA}$$

$$V = 2647.2(4) \text{ \AA}^3$$

For Z = 4 and F.W. = 479.65, the calculated density is 1.203 g/cm<sup>3</sup>. The reflection conditions of:

$$h0l: h+l=2n$$

$$0k0: k=2n$$

uniquely determine the space group to be:

## P2<sub>1</sub>/n (#14)

The data were collected at a temperature of -100  $\pm$  1°C to a maximum 2θ value of 50.8°. Readout was performed in the 0.172 mm pixel mode.

### Data Reduction

Of the 31247 reflections were collected, where 4854 were unique ( $R_{\text{int}} = 0.0379$ ); equivalent reflections were merged. Data were collected and processed using CrystalClear (Rigaku).<sup>1</sup>

The linear absorption coefficient,  $\mu$ , for Mo-Kα radiation is 14.341 cm<sup>-1</sup>. An empirical absorption correction was applied which resulted in transmission factors ranging from 0.877 to 0.958. The data were corrected for Lorentz and polarization effects.

### Structure Solution and Refinement

The structure was solved by direct methods<sup>2</sup> and expanded using Fourier techniques. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using the riding model. The final cycle of full-matrix least-squares refinement<sup>3</sup> on  $F^2$  was based on 4854 observed reflections and 271 variable parameters and converged (largest parameter shift was 0.00 times its esd) with unweighted and weighted agreement factors of:

$$R_1 = \sum | |F_O| - |F_C| | / \sum |F_O| = 0.0704$$

$$wR_2 = [ \sum (w(F_O^2 - F_C^2)^2) / \sum w(F_O^2)^2 ]^{1/2} = 0.2216$$

The goodness of fit<sup>4</sup> was 1.07. Unit weights were used. Plots of  $\sum w(|F_O| - |F_C|)^2$  versus |F<sub>O</sub>|, reflection order in data collection,  $\sin \theta/\lambda$  and various classes of indices showed no unusual trends. The maximum and minimum peaks on the final difference Fourier map corresponded to 1.71 and -0.54 e<sup>-</sup>/Å<sup>3</sup>, respectively.

Neutral atom scattering factors were taken from International Tables for Crystallography (IT), Vol. C, Table 6.1.1.4.<sup>5</sup> Anomalous dispersion effects were included in F<sub>calc</sub><sup>6</sup>; the values for Δf' and Δf'' were those of Creagh and McAuley.<sup>7</sup> The values for the mass attenuation coefficients are those of Creagh and Hubbell.<sup>8</sup> All calculations were performed using the CrystalStructure<sup>9</sup> crystallographic software package except for refinement, which was performed using SHELXL2013.<sup>10</sup>

$$c = 13.6459(19) \text{ \AA}$$

$$V = 834.42(19) \text{ \AA}^3$$

For  $Z = 2$  and F.W. = 355.34, the calculated density is  $1.414 \text{ g/cm}^3$ . Based on the reflection conditions of:

$$h0l: h+l = 2n$$

packing considerations, a statistical analysis of intensity distribution, and the successful solution and refinement of the structure, the space group was determined to be:

$$P2/n (\#13)$$

The data were collected at a temperature of  $-100 \pm 10^{\circ}\text{C}$  to a maximum  $2\theta$  value of  $50.7^{\circ}$ . Readout was performed in the 0.172 mm pixel mode.

Of the 9772 reflections were collected, where 1532 were unique ( $R_{\text{int}} = 0.0564$ ); equivalent reflections were merged. Data were collected and processed using CrystalClear (Rigaku).<sup>1</sup>

The linear absorption coefficient,  $\mu$ , for Mo-K $\alpha$  radiation is  $22.487 \text{ cm}^{-1}$ . An empirical absorption correction was applied which resulted in transmission factors ranging from 0.655 to 0.956. The data were corrected for Lorentz and polarization effects.

## Structure Solution and Refinement

The structure was solved by heavy-atom Patterson methods<sup>2</sup> and expanded using Fourier techniques. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using the riding model. The final cycle of full-matrix least-squares refinement<sup>3</sup> on  $F^2$  was based on 1532 observed reflections and 103 variable parameters and converged (largest parameter shift was 0.00 times its esd) with unweighted and weighted agreement factors of:

$$R1 = \sum | |F_O| - |F_C| | / \sum |F_O| = 0.0277$$

$$wR2 = [ \sum (w(F_O^2 - F_C^2)^2) / \sum w(F_O^2)^2 ]^{1/2} = 0.0736$$

The goodness of fit<sup>4</sup> was 1.02. Unit weights were used. Plots of  $\sum w(|F_O| - |F_C|)^2$  versus  $|F_O|$ , reflection order in data collection,  $\sin \theta/\lambda$  and various classes of indices showed no unusual trends. The maximum and minimum peaks on the final difference Fourier map corresponded to 0.54 and -0.26 e<sup>-</sup>/Å<sup>3</sup>, respectively.

A yellow prism crystal of C<sub>21</sub>H<sub>24</sub>N<sub>2</sub>Se having approximate dimensions of 0.150 x 0.060 x 0.060 mm was mounted in a loop. All measurements were made on a Rigaku XtaLAB P200 diffractometer using multi-layer mirror monochromated Mo-Kα radiation.

Cell constants and an orientation matrix for data collection corresponded to a primitive orthorhombic cell with dimensions:

$$a = 16.043(2) \text{ Å}$$

$$b = 7.3937(9) \text{ Å}$$

$$c = 16.055(2) \text{ Å}$$

$$V = 1904.3(4) \text{ Å}^3$$

For Z = 4 and F.W. = 383.39, the calculated density is 1.337 g/cm<sup>3</sup>. The reflection conditions of:

$$0kl: k = 2n$$

$$h0l: l = 2n$$

$$hk0: h+k = 2n$$

uniquely determine the space group to be:

Pbcn (#60)

The data were collected at a temperature of -100 ± 1°C to a maximum 2θ value of 50.8°. Readout was performed in the 0.172 mm pixel mode.

### Data Reduction

Of the 21284 reflections were collected, where 1745 were unique ( $R_{int} = 0.0597$ ); equivalent reflections were merged. Data were collected and processed using CrystalClear (Rigaku). <sup>1</sup>

The linear absorption coefficient,  $\mu$ , for Mo-Kα radiation is 19.760 cm<sup>-1</sup>. An empirical absorption correction was applied which resulted in transmission factors ranging from 0.749 to 0.888. The data were corrected for Lorentz and polarization effects.

### Structure Solution and Refinement

The structure was solved by direct methods<sup>2</sup> and expanded using Fourier techniques. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using the riding model. #### Data Collection

A colorless prism crystal of C<sub>35</sub>H<sub>52</sub>N<sub>2</sub>Se having approximate dimensions of 0.150 x 0.060 x 0.020 mm was mounted in a loop. All measurements were made on a Rigaku XtaLAB P200 diffractometer using multi-layer mirror monochromated Mo-K $\alpha$  radiation.

Cell constants and an orientation matrix for data collection corresponded to a primitive monoclinic cell with dimensions:

$$a = 20.433(2) \text{ \AA}$$

$$b = 7.6327(6) \text{ \AA} \quad \beta = 106.660(3)^{\circ}$$

$$c = 21.563(2) \text{ \AA}$$

$$V = 3221.7(6) \text{ \AA}^3$$

For Z = 4 and F.W. = 579.77, the calculated density is 1.195 g/cm<sup>3</sup>. The reflection conditions of:

$$h0l: l = 2n$$

$$0k0: k = 2n$$

uniquely determine the space group to be:

$$P2_1/c (\#14)$$

The data were collected at a temperature of -100  $\pm$  1°C to a maximum 2 $\theta$  value of 50.8°. Readout was performed in the 0.172 mm pixel mode.

## Data Reduction

Of the 37896 reflections were collected, where 5921 were unique ( $R_{\text{int}} = 0.0499$ ); equivalent reflections were merged. Data were collected and processed using CrystalClear (Rigaku).<sup>1</sup>

The linear absorption coefficient,  $\mu$ , for Mo-K $\alpha$  radiation is 11.901 cm $^{-1}$ . An empirical absorption correction was applied which resulted in transmission factors ranging from 0.867 to 0.976. The data were corrected for Lorentz and polarization effects.

## Structure Solution and Refinement

The structure was solved by heavy-atom Patterson methods<sup>2</sup> and expanded using Fourier techniques. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using the riding model. The final cycle of full-matrix least-squares refinement<sup>3</sup> on  $F^2$  was based on 5921 observed reflections and 351 variable parameters and converged (largest parameter shift was 0.00 times its esd) with unweighted and weighted agreement factors of:

$$R_1 = \sum | |F_O| - |F_C| | / \sum |F_O| = 0.0448$$

$$wR_2 = [ \sum (w(F_O^2 - F_C^2)^2) / \sum w(F_O^2)^2 ]^{1/2} = 0.1139$$

The goodness of fit<sup>4</sup> was 1.03. Unit weights were used. Plots of  $\sum w (|F_O| - |F_C|)^2$  versus  $|F_O|$ , reflection order in data collection,  $\sin \theta/\lambda$  and various classes of indices showed no unusual trends. The maximum and minimum peaks on the final difference Fourier map corresponded to 0.63 and -0.33 e $^-$ /Å $^3$ , respectively.

Neutral atom scattering factors were taken from International Tables for Crystallography (IT), Vol. C, Table 6.1.1.4<sup>5</sup>. Anomalous dispersion effects were included in  $F_{\text{calc}}$ <sup>6</sup>; the values for  $\Delta f'$  and  $\Delta f''$  were those of Creagh and McAuley<sup>7</sup>. The values for the mass attenuation coefficients are those of Creagh and Hubbell<sup>8</sup>. All calculations were performed using the CrystalStructure<sup>9</sup> crystallographic software package except for refinement, which was performed using SHELXL2013<sup>10</sup>.

The final cycle of full-matrix least-squares refinement<sup>3</sup> on  $F^2$  was based on 2221 observed reflections and 181 variable parameters and converged (largest parameter shift was 0.00 times its esd) with unweighted and weighted agreement factors of:

$$R1 = \sum | |F_O| - |F_C| | / \sum |F_O| = 0.0480$$

$$wR2 = [ \sum (w(F_O^2 - F_C^2)^2) / \sum w(F_O^2)^2 ]^{1/2} = 0.1182$$

The goodness of fit<sup>4</sup> was 0.96. Unit weights were used. Plots of  $\sum w (|F_O| - |F_C|)^2$  versus  $|F_O|$ , reflection order in data collection,  $\sin \theta/\lambda$  and various classes of indices showed no unusual trends. The maximum and minimum peaks on the final difference Fourier map corresponded to  $1.30$  and  $-0.30 \text{ e}^-/\text{\AA}^3$ , respectively.

Neutral atom scattering factors were taken from International Tables for Crystallography (IT), Vol. C, Table 6.1.1.4<sup>5</sup>. Anomalous dispersion effects were included in  $F_{\text{calc}}$ <sup>6</sup>; the values for  $\Delta f'$  and  $\Delta f''$  were those of Creagh and McAuley<sup>7</sup>. The values for the mass attenuation coefficients are those of Creagh and Hubbell<sup>8</sup>. All calculations were performed using the CrystalStructure<sup>9</sup> crystallographic software package except for refinement, which was performed using SHELXL2013<sup>10</sup>.

#### Data Collection

A colorless platelet crystal of  $C_{11}H_{11}N_3OSe$  having approximate dimensions of 0.100 x 0.090 x 0.020 mm was mounted in a loop. All measurements were made on a Rigaku XtaLAB P200 diffractometer using multi-layer mirror monochromated Mo-K $\alpha$  radiation.

Cell constants and an orientation matrix for data collection corresponded to a primitive triclinic cell with dimensions:

$$a = 7.8283(13) \text{ \AA} \quad \alpha = 97.930(6)^\circ$$

$$b = 7.9731(14) \text{ \AA} \quad \beta = 94.637(5)^\circ$$

$$c = 18.447(3) \text{ \AA} \quad \gamma = 90.042(5)^\circ$$

$$V = 1136.6(4) \text{ \AA}^3$$

For Z = 4 and F.W. = 280.19, the calculated density is 1.637 g/cm<sup>3</sup>. Based on a statistical analysis of intensity distribution, and the successful solution and refinement of the structure, the space group was determined to be:

$$P-1 (\#2)$$

The data were collected at a temperature of -100  $\pm$  1°C to a maximum 2 $\theta$  value of 51.0°. Readout was performed in the 0.172 mm pixel mode.

#### Data Reduction

Of the 13206 reflections were collected, where 4171 were unique ( $R_{\text{int}} = 0.1195$ ); equivalent reflections were merged. Data were collected and processed using CrystalClear (Rigaku).<sup>1</sup>

The linear absorption coefficient,  $\mu$ , for Mo-K $\alpha$  radiation is 32.859 cm<sup>-1</sup>. An empirical absorption correction was applied which resulted in transmission factors ranging from 0.536 to 0.936. The data were corrected for Lorentz and polarization effects.

#### Structure Solution and Refinement

The structure was solved by heavy-atom Patterson methods<sup>2</sup> and expanded using Fourier techniques.

The crystal is a non-merohedral twin with twin law:

1.00000 0.00000 0.00000  
0.00000 -1.00000 0.00000  
0.38100 0.63900 1.00000

Twin component #1 comprises 12.02% of the crystal.

The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using the riding model. The final cycle of full-matrix least-squares refinement<sup>3</sup> on  $F^2$  was based on 4171 observed reflections and 290 variable parameters and converged (largest parameter shift was 0.00 times its esd) with unweighted and weighted agreement factors of:

$$R1 = \sum | |F_O| - |F_C| | / \sum |F_O| = 0.1235$$

$$wR2 = [ \sum (w (F_O^2 - F_C^2)^2) / \sum w(F_O^2)^2 ]^{1/2} = 0.3513$$

The goodness of fit<sup>4</sup> was 1.17. Unit weights were used. Plots of  $\sum w (|F_O| - |F_C|)^2$  versus  $|F_O|$ , reflection order in data collection,  $\sin \theta/\lambda$  and various classes of indices showed no unusual trends. The maximum and minimum peaks on the final difference Fourier map corresponded to 2.49 and -1.17 e<sup>-</sup>/Å<sup>3</sup>, respectively.

Neutral atom scattering factors were taken from International Tables for Crystallography (IT), Vol. C, Table 6.1.1.4<sup>5</sup>. Anomalous dispersion effects were included in  $F_{\text{calc}}$ <sup>6</sup>; the values for  $\Delta f'$  and  $\Delta f''$  were those of Creagh and McAuley<sup>7</sup>. The values for the mass attenuation coefficients are those of Creagh and Hubbell<sup>8</sup>. The detector swing angle was  $-10.42^\circ$ . The crystal-to-detector distance was 45.02 mm. Readout was performed in the 0.086 mm pixel mode.

## Data Reduction

Of the 64470 reflections were collected, where 5063 were unique ( $R_{\text{int}} = 0.0445$ ); equivalent reflections were merged. Data were collected and processed using CrystalClear (Rigaku).<sup>1</sup>

The linear absorption coefficient,  $\mu$ , for Mo-K $\alpha$  radiation is 14.272 cm $^{-1}$ . An empirical absorption correction was applied which resulted in transmission factors ranging from 0.824 to 0.867. The data were corrected for Lorentz and polarization effects.

## Structure Solution and Refinement

The structure was solved by heavy-atom Patterson methods<sup>2</sup> and expanded using Fourier techniques. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using the riding model. The final cycle of full-matrix least-squares refinement<sup>3</sup> on  $F^2$  was based on 5063 observed reflections and 330 variable parameters and converged (largest parameter shift was 0.00 times its esd) with unweighted and weighted agreement factors of:

$$R1 = \sum | |F_O| - |F_C| | / \sum |F_O| = 0.0248$$

$$wR2 = [ \sum (w(F_O^2 - F_C^2)^2) / \sum w(F_O^2)^2 ]^{1/2} = 0.0616$$

The goodness of fit<sup>4</sup> was 1.05. Unit weights were used. Plots of  $\sum w(|F_O| - |F_C|)^2$  versus  $|F_O|$ , reflection order in data collection,  $\sin \theta/\lambda$  and various classes of indices showed no unusual trends. The maximum and minimum peaks on the final difference Fourier map corresponded to 0.29 and -0.25 e $^-$ /Å $^3$ , respectively.

Neutral atom scattering factors were taken from International Tables for Crystallography (IT), Vol. C, Table 6.1.1.4<sup>5</sup>. Anomalous dispersion effects were included in  $F_{\text{calc}}$ <sup>6</sup>; the values for  $\Delta f'$  and  $\Delta f''$  were those of Creagh and McAuley<sup>7</sup>. The values for the mass attenuation coefficients are those of Creagh and Hubbell<sup>8</sup>. All calculations were performed using the CrystalStructure<sup>9</sup> crystallographic software package except for refinement, which was performed using SHELXL2013<sup>10</sup>.

## Computational Details

All calculations have been performed using density functional theory (DFT) with the gradient corrections for exchange and correlation proposed by Becke<sup>9</sup> and Perdew<sup>10</sup> (BP86), as implemented in the ADF package,<sup>11-13</sup> in combination with a fine integration parameter (with a numerical integration parameter set to 5). A triple- $\xi$  basis set with two polarization functions on all atoms (TZ2P) was used. Electrons of the core shells have been treated within the frozen core approximation.<sup>14</sup> All geometries were initially optimized without any symmetry constraint. These geometries were used to obtain the Se/P NMR chemical shielding properties, and the molecular orbital energy gap [Se(p<sub>y</sub>) → Se-NHC( $\pi^*$ )] in the case of selenoureas. Atomic partial charges have been calculated with the Hirshfeld partitioning scheme.<sup>15</sup>

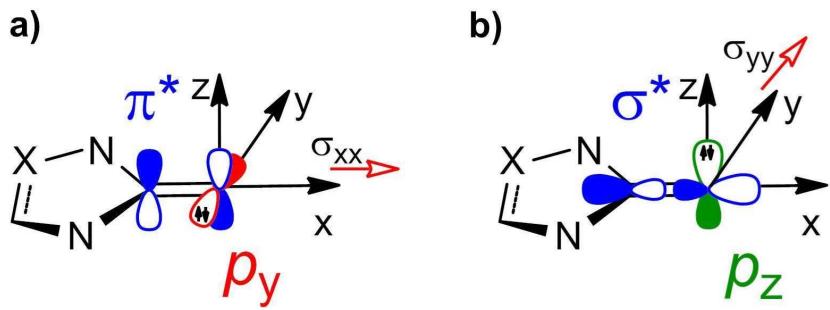

As discussed in the main text, the major changes to the total isotropic shielding between the different systems are due to changes in the paramagnetic component ( $\sigma_p$ ). To understand the impact of the nature of the NHC ligand on the Se paramagnetic shielding, we thus compared three systems chosen to cover the NMR scale of **Figure 2**. Namely, **I*i*Pr<sup>Me</sup>**, **SIMes** and **SIPr**, with  $\delta_{\text{Se}}$  equal to -18, 110 and 190 ppm, respectively. For the sake of simplicity in the analysis, the systems were re-optimized under the constraint of C<sub>3</sub> symmetry, with the NHC ligand located in the  $\sigma_{xy}$  mirror plane of the molecule. As indicated in the main text, this results in minor differences in energy and NMR total isotropic shielding.

The principal components of total paramagnetic tensor of the Se atom in the three systems, reported in **Table S1**, clearly indicates that the  $\sigma_{yy}$  and  $\sigma_{zz}$  components in the three systems are roughly the same, with a change of only 80 ppm in  $\sigma_{yy}$ , while the major change is in the  $\sigma_{xx}$  component, that spans a range of about 700 ppm, and nicely matching the trend in the experimental  $\delta_{\text{Se}}$  values.

**Table S1.** Experimental chemical shift and principal components of total DFT paramagnetic tensor of the Se atom in selected NHC-Se adducts. Systems oriented as in **Figure S1**.

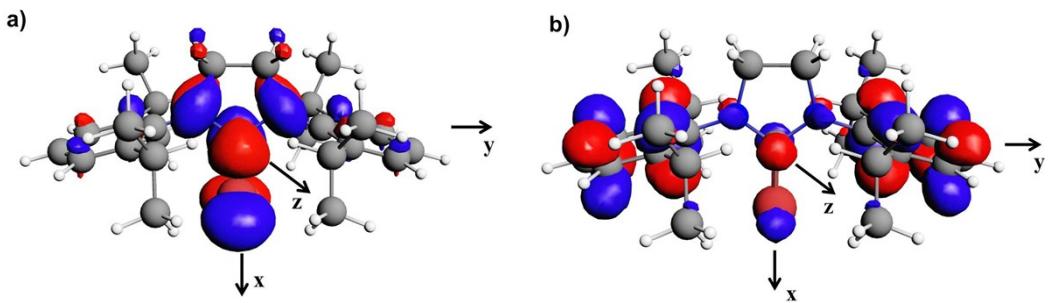

System	$\delta_{\text{Se}}$ (ppm)	$\sigma_{xx}$ (ppm)	$\sigma_{yy}$ (ppm)	$\sigma_{zz}$ (ppm)
<b>I<i>i</i>Pr</b>	-18	-1062	-1947	-1177
<b>SIMes</b>	110	-1394	-2028	-1194
<b>SIPr</b>	190	-1751	-2027	-1190

Analysis of the orbitals contributing to the change of the  $\sigma_{xx}$  component of the paramagnetic tensor indicated that the major contributions stem from coupling of occupied and virtual orbitals, specifically from the Se(p<sub>y</sub>) → Se-NHC( $\pi^*$ ) transition sketched in **Figure S1**.

**Figure S1.** (a) Schematic representation of the occupied-virtual  $\text{Se}(p_y) \rightarrow \text{Se-NHC}(\pi^*)$  transition, which contributes to the  $\sigma_{xx}$  component of the paramagnetic tensor. (b) Schematic representation of the occupied-virtual  $\text{Se}(p_z) \rightarrow \text{NHC-Se}(\sigma^*)$  orbital, which contributes to the  $\sigma_{yy}$  component of the paramagnetic tensor.

However, in the case of the **iPr<sup>Me</sup>** system the  $\text{Se-NHC}(\pi^*)$  orbital combination is well localized in a single molecular orbital, see **Figure 6c** in the main text, and thus only one  $\text{Se}(p_y) \rightarrow \text{Se-NHC}(\pi^*)$  transition contributes to the  $\sigma_{xx}$  component. Differently, in the **SIMes** and **SIPr** systems, the  $\text{Se-NHC}(\pi^*)$  orbital combination is spread over at least two virtual molecular orbitals, see **Figure S2**, and both these virtual orbitals participate to the  $\sigma_{xx}$  component of the paramagnetic tensor through  $\text{Se}(p_y) \rightarrow \text{Se-NHC}(\pi^*)$  transitions. Finally, the large value of the  $\sigma_{yy}$  component of the paramagnetic tensor corresponds to a transition from the occupied  $\text{Se}(p_z)$  orbital to the a  $\text{NHC-Se}(\sigma^*)$  orbital, see **Figure S1**, and it is quite independent of the nature of the NHC ligand. In conclusion, this analysis indicates that variation in the Se chemical shielding are related to the  $\text{Se}(p_y) \rightarrow \text{Se-NHC}(\pi^*)$  energy gap, supporting the analysis performed in **Figure 7** of the main text. For completeness, the above orbital analysis and decomposition of the total paramagnetic shielding has been performed on the optimized geometries through single point energy calculations using all electrons basis sets and scalar relativistic ZORA effects.<sup>16-20</sup> Further, the energy gaps of **Figure 7** have been evaluated by including solvent effects,  $\text{CHCl}_3$ , through the continuum solvation model COSMO.<sup>21</sup>

**Figure S2.** Representation of the virtual orbitals presenting a strong Se-NHC( $\pi^*$ ) characters, and participating to the occupied-virtual  $\text{Se}(p_y) \rightarrow \text{NHC-Se}(\pi^*)$  transitions that contribute to the  $\sigma_{xx}$  component of the paramagnetic tensor.

To better understand the nature of chemical bonding in selenoureas and phosphinidene complexes, we have analyzed the bonding interaction between the NHC and Se atom or PPh fragments using a bonding energy decomposition analysis (BDA), originally developed by Morokuma<sup>22,23</sup> and later modified by Ziegler and Rauk.<sup>24</sup> The BDA is based on the interaction of two fragments rigidly extracted from the equilibrium geometry of the system, and which both have an electronic structure suitable for bond formation. This interaction energy is usually referred to as the bond snapping energy.<sup>25</sup> Although the bond snapping energy does not always correlate with the bond dissociation enthalpy, because the relaxation and the reorganization energy of the two fragments are not considered, the bond snapping energy is closely related to the bond enthalpy, which usually is a good approximation to bond strength values. Further, the bond snapping energy (BSE) can be decomposed into two main terms, namely steric interaction  $\Delta E_0$  and orbital interaction  $\Delta E_{\text{int}}$  (Eq. S1).

$$\text{BSE} = -[\Delta E_0 + \Delta E_{\text{int}}] \quad (\text{S1})$$

While further elaboration of Eq. S1 is possible, for the present analysis we will limit to the partitioning scheme outlined in Eq. S1. The total orbital interaction energy  $\Delta E_{\text{int}}$  can further be broken down into contributions from the orbital interactions within the various irreducible representations  $\Gamma$  of the overall symmetry group of the system<sup>26</sup> (Eq. S2).

$$\Delta E_{\text{int}} = \sum_{\Gamma} \Delta E_{\text{int}}^{\Gamma} \quad (\text{S2})$$

For  $\Delta E_{\text{int}}$  analysis, the geometries of all the complexes were re-optimized under the constraint of  $C_S$  symmetry; the NHC ligand is located in the  $\sigma_{xy}$  mirror plane of the molecule. Therefore,  $A'$  contributions to the orbital interaction energy are associated with  $\sigma$ -bonding and  $A''$  contributions represent  $\pi$ -interactions between the NHC and either the Se atom or the PPh fragment. For the latter, the phenyl ring was oriented perpendicular to the  $\sigma_{xy}$  plane.

[a]  $E_{\sigma}$ -Pred is the predicted  $E_{\sigma}$  using the equation of straight line [ $y = E_{\sigma}$ -Pred =  $(-0.0226 * (x = \text{DFT } \delta) + -239.36)$ ]. [b] Residuals are calculated as the difference between the  $E_{\sigma}$ -Pred and  $E_{\sigma}$  values, i.e.,  $E_i(E_{\sigma}\text{-Pred}) - E_i(E_{\sigma})$ . [c]  $E_{\pi}$ -Pred is the predicted  $E_{\pi}$  using the equation of straight line [ $y = E_{\pi}$ -Pred =  $(0.0233 * (x = \text{DFT } \delta) + -124.63)$ ]. [d] Residuals are calculated as the difference between the  $E_{\pi}$ -Pred and  $E_{\pi}$  values, i.e.,  $E_i(E_{\pi}\text{-Pred}) - E_i(E_{\pi})$ . [e] Se(I*i*Bu) and Se(IAd) are the possible outliers due to large residual errors (shown in red color) thus excluded from the analysis.). [f]  $E_{\pi}$ -PredF is the final predicted  $E_{\pi}$  obtained by using the equation of straight line [ $y = E_{\pi}$ -PredF =  $(0.0321 * (x = \text{DFT } \delta) + -138.07)$ ]. For triazoles,  $E_{\sigma}$ -Pred is obtained by using the equation of straight line [ $y = E_{\sigma}$ -Pred =  $(-0.0408 * (x = \text{Se DFT } \delta) + -207.85)$ ], while  $E_{\pi}$ -PredF is obtained by using [ $y = E_{\pi}$ -PredF =  $(0.1106 * (x = \text{DFT } \delta) + -259.72)$ ].
