## Supplementary Information

### **Procedure to determine the surface composition from surface tension measurements**

Measuring the surface tension  $\sigma$  (a) as a function of the total surfactant concentration  $c$  for a binary surfactant mixture enables the calculation of the total adsorbed amount of the mixture ( $\Gamma_{\text{total}}$ ) at the surface and (b) as a function of the concentration of surfactant 2 keeping the concentration of surfactant 1 constant allows us to calculate the adsorbed amount of surfactant 2 at the surface. Hence the amount of surfactant 1 adsorbed at the surface can simply be evaluated by subtracting the amount of surfactant 2 adsorbed at the surface from the total adsorbed amount of the mixture ( $\Gamma_{\text{total}}$ ). This approach was the basis for the determination of the surfactant composition at the surface for both binary surfactant mixtures studied and will be described in detail in the following.

#### **i) $\beta$ -C<sub>12</sub>G<sub>2</sub> / C<sub>12</sub>TAB surfactant mixture**

In Fig.1 (left) the surface tensions  $\sigma$  are shown as a function of the total surfactant concentration  $c$  for the pure  $\beta$ -C<sub>12</sub>G<sub>2</sub>, the pure C<sub>12</sub>TAB, and for three surfactant mixtures at bulk mole fractions of  $\alpha_1 = 0.02, 0.50, \text{ and } 0.98$ . In Fig. 1 (right) the surface tensions of the surfactant mixtures measured as a function of the sugar surfactant concentration  $c(\beta\text{-C}_{12}\text{G}_2)$  at a constant C<sub>12</sub>TAB concentration  $c(\text{C}_{12}\text{TAB})$  are seen. All solid lines in Fig.1 are fits of the experimental data carried out with a second order polynomial. As mentioned above, these fits allow us to determine the total adsorbed amount at the cmc ( $\Gamma_{\text{total,cmc}}$ ) as well as the adsorbed amount of  $\beta$ -C<sub>12</sub>G<sub>2</sub> ( $\Gamma_{\text{C}_{12}\text{G}_2,\text{cmc}}$ ) at the cmc for the three mixtures. Subtracting  $\Gamma_{\text{C}_{12}\text{G}_2,\text{cmc}}$  from  $\Gamma_{\text{total,cmc}}$  leads to  $\Gamma_{\text{C}_{12}\text{TAB,cmc}}$ . For the pure surfactants, the total adsorbed amounts  $\Gamma_{\text{total,cmc}}$  were obtained by treating  $\beta$ -C<sub>12</sub>G<sub>2</sub> as non-ionic and C<sub>12</sub>TAB as ionic surfactant using eq S1 and eq S2, respectively.

It holds

$$\left( \frac{d\sigma}{d \ln c_{C_{12}G_2}} \right) = -RT \Gamma_{C_{12}G_2} \quad (S1)$$

and

$$\left( \frac{d\sigma}{d \ln c_{C_{12}TAB}} \right) = -2RT \Gamma_{C_{12}TAB} . \quad (S2)$$

For the mixtures, the total adsorbed amounts  $\Gamma_{\text{total,cmc}}$  and the adsorbed amounts of the individual components ( $\Gamma_{C_{12}G_2,\text{cmc}}$  and  $\Gamma_{C_{12}TAB,\text{cmc}}$ ) were obtained with eqs S3 and S4, assuming ideal bulk behaviour and neglecting the contribution of the ionic charge of  $C_{12}TAB$ .

It holds<sup>6</sup>

$$\left( \frac{d\sigma}{d \ln c_{C_{12}G_2}} \right)_{C_{12}TAB} = -RT \Gamma_{C_{12}G_2} \quad (S3)$$

and

$$\left( \frac{d\sigma}{d \ln c_{\text{total}}} \right)_{C_{12}TAB/C_{12}G_2} = -RT \Gamma_{\text{total}} . \quad (S4)$$

## ii) $\beta$ - $C_{12}G_2$ / $C_{12}E_6$ surfactant mixture

In Fig.S1 (left) the surface tension  $\sigma$  of a 1:1 mixture ( $\alpha_1 = 0.50$ ) is plotted as a function of the total surfactant concentration  $c$ . The slope at each single point of this curve gives us  $\Gamma_{\text{total}}$ . As an example the slope at a total surfactant concentration of  $1.0 \cdot 10^{-5}$  M is shown. At this concentration the bulk concentrations of both surfactants are  $5.0 \cdot 10^{-6}$  M. The next step is to fix one of the two bulk concentrations and vary the concentration of the second surfactant. In our case we measured the surface tension  $\sigma$  as a function of the total  $C_{12}E_6$  concentration at a constant  $\beta$ - $C_{12}G_2$  concentration of  $c(\beta\text{-}C_{12}G_2) = 5.0 \cdot 10^{-6}$  M (Fig.S1 (right)). Note that the highest  $\sigma$  value is  $65 \text{ mN m}^{-1}$ , which corresponds to the value of the pure  $\beta$ - $C_{12}G_2$  solution at

$c = 5.0 \cdot 10^{-6}$  M (see Fig.3 (left)). The slope of the  $\sigma$ - $c(\text{C}_{12}\text{E}_6)$  curve at a  $\text{C}_{12}\text{E}_6$  concentration of  $c(\text{C}_{12}\text{E}_6) = 5.0 \cdot 10^{-6}$  M gives us  $\Gamma_{\text{C}_{12}\text{E}_6}$ . Thus the adsorbed amount of  $\beta$ - $\text{C}_{12}\text{G}_2$  ( $\Gamma_{\text{C}_{12}\text{G}_2}$ ) for the 1:1 mixture at a total surfactant concentration of  $1.0 \cdot 10^{-5}$  M can simply be calculated by subtracting  $\Gamma_{\text{C}_{12}\text{E}_6}$  from  $\Gamma_{\text{total}}$ . This procedure was used to determine the surfactant composition at the surface for other mixing ratios all of which are represented in Fig.4.

**Table S1.** Critical micelle concentrations (cmc), total adsorbed amount at the cmc ( $\Gamma_{\text{total,cmc}}$ ) of the pure and the mixed surfactant systems, adsorbed amount of  $\beta$ -C<sub>12</sub>G<sub>2</sub> at the cmc ( $\Gamma_{\text{C12G2,cmc}}$ ) and adsorbed amount of C<sub>12</sub>TAB at the cmc ( $\Gamma_{\text{C12TAB,cmc}}$ ). Data are extracted from the  $\sigma$ - $c$  curves shown in Fig.1.  $\alpha_1$  is the bulk mole fraction of C<sub>12</sub>TAB in the mixture.  $X_1^\sigma$  ( $X_2^\sigma$ ) is the mole fraction of C<sub>12</sub>TAB ( $\beta$ -C<sub>12</sub>G<sub>2</sub>) in the mixed surface.

$\alpha_1$	1.00	0.98	<b>0.50</b>	0.02	0
cmc / M	$1.5 \cdot 10^{-2}$	$5.1 \cdot 10^{-3}$	<b><math>3.0 \cdot 10^{-4}</math></b>	$1.5 \cdot 10^{-4}$	$1.5 \cdot 10^{-4}$
$\Gamma_{\text{total,cmc}} / \text{mol m}^{-2}$	$3.9 \cdot 10^{-6}$	$4.4 \cdot 10^{-6}$ ( $2.2 \cdot 10^{-6}$ ) <sup>a</sup>	<b><math>4.0 \cdot 10^{-6}</math></b> ( <b><math>2.0 \cdot 10^{-6}</math></b> ) <sup>a</sup>	$4.2 \cdot 10^{-6}$ ( $2.1 \cdot 10^{-6}$ ) <sup>a</sup>	$4.2 \cdot 10^{-6}$

$X_2^\sigma$	0	0.6	<b>0.9</b>	~1.0	1.0

<sup>a</sup> Mixture was treated as if it were purely ionic. See text for further details.

The results reported in bold were evaluated by a combination of surface tension measurement and foam film measurements<sup>3</sup>

**Table S2.** Critical micelle concentrations (cmc) and total adsorbed amount at the cmc ( $\Gamma_{\text{total,cmc}}$ ) of the pure surfactants and the  $\beta$ -C<sub>12</sub>G<sub>2</sub> / C<sub>12</sub>E<sub>6</sub> mixed surfactant system. Data are extracted from the  $\sigma$ - $c$  curves shown in Fig.3 (left).  $\alpha_1$  is the bulk mole fraction of C<sub>12</sub>E<sub>6</sub> in the mixture.

$\alpha_1$	0.00	0.20	0.40	0.50	0.80	1.00
cmc / M	$1.5 \cdot 10^{-4}$	$1.2 \cdot 10^{-4}$	$1.1 \cdot 10^{-4}$	$1.0 \cdot 10^{-4}$	$8.5 \cdot 10^{-5}$	$7.3 \cdot 10^{-5}$
$\Gamma_{\text{total,cmc}} / \text{mol m}^{-2}$	$4.20 \cdot 10^{-6}$	$4.08 \cdot 10^{-6}$	$3.93 \cdot 10^{-6}$	$3.80 \cdot 10^{-6}$	$3.75 \cdot 10^{-6}$	$3.30 \cdot 10^{-6}$

## Figure Caption

**Figure S1.** Surface tension  $\sigma$  as a function of total surfactant concentration  $c$  for aqueous solutions of a 1:1 mixture ( $\alpha_1 = 0.5$ ) of  $\beta$ -C<sub>12</sub>G<sub>2</sub> and C<sub>12</sub>E<sub>6</sub> (left) and surface tension  $\sigma$  as a function of the total C<sub>12</sub>E<sub>6</sub> concentration at a constant  $\beta$ -C<sub>12</sub>G<sub>2</sub> concentration of  $c(\beta\text{-C}_{12}\text{G}_2) = 5.0 \cdot 10^{-6}$  M (right). All solid lines represent fits of the experimental data carried out with a polynomial of second order.
