Complementary TEM experiments

For a better understanding of the local influence of Pd NPs on their surrounding porosity, a detailed analysis of the general aspect of the carbon matrix above and below the Pd particles is shown in Figure SI1. The slices presented in Figures SI1a and SI1c show clearly that before and after several nm thickness from the NPs (Figure SI1b), the general aspect of the C support is the same as in areas containing no Pd particles. It confirms that the particles are surrounded by large voids within the C support with local distortion of the worm-like mesoporous framework around them.

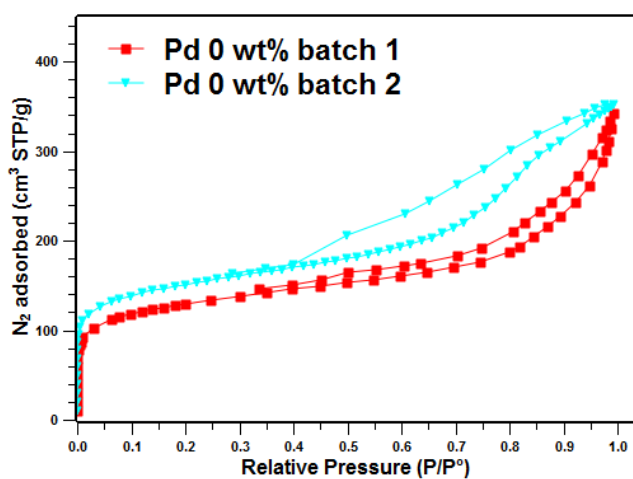

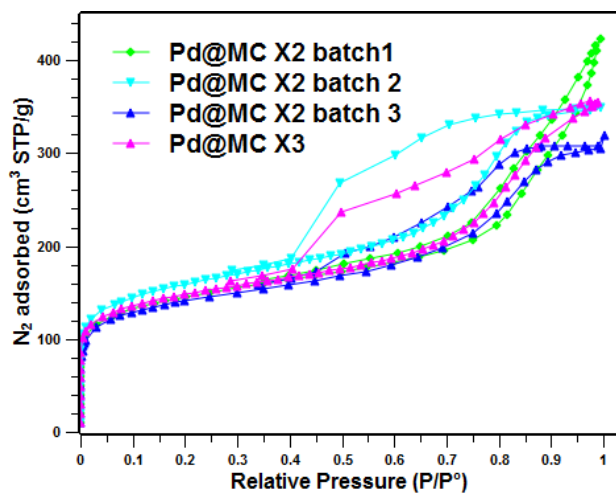

Figure SI1. Representative slices details extracted from the reconstructed volume of Pd@MC X3 sample to evidence the influence of metallic Pd nanoparticles on the porosity: a) slice at thickness $e_0 - 32 \text{ nm}$; b) slice of reference at thickness e_0 and b) slice at thickness $e_0 + 44 \text{ nm}$. The scale in the three slices is 100 nm.

Figure S12: N₂ adsorption/desorption isotherms measured at 77K on (a) tanin-derived carbon samples and, (b) Pd@MC Xi samples. The figure evidences the variability of the synthesis and the negligible influence of Pd²⁺ traces on the pore size distribution.
